Abstract:	<p>This paper investigates employees seeking problem-solving assistance from colleagues with whom they find it difficult to work. In so doing, the paper introduces the construct of dissonant ties: network ties to colleagues that are simultaneously positive and negative. The study builds on the assumption that individuals in knowledge-intensive workplaces employ dissonant ties to access distinct work-related benefits, and establishes a link between dissonant ties and performance. Subsequently, it provides an in-depth analysis of employees' willingness to rely on this potentially unpleasant but instrumental networking behavior, and suggests that formal hierarchical rank, tenure, and unit membership as critical elements of the organizational architecture drive dissonant tie formation. In the empirical analysis, the study utilizes survey and interview data collected from engineers in a large manufacturing firm. The findings confirm that seeking problem-solving assistance from difficult colleagues entails performance benefits. Moreover, the embeddedness of individuals in the organizational architecture shapes the employment of dissonant ties. Dissonant ties are, hence, context driven. By simultaneously addressing the consequences and the drivers of employees' networking behavior, the study presents a comprehensive theory of dissonant ties that challenges and refines previous research on the interplay between positive and negative networks.</p>

7

8 **ABSTRACT**

9 This paper investigates employees seeking problem-solving assistance from colleagues
10 with whom they find it difficult to work. In so doing, the paper introduces the construct of
11 dissonant ties: network ties to colleagues that are simultaneously positive and negative. The
12 study builds on the assumption that individuals in knowledge-intensive workplaces employ
13 dissonant ties to access distinct work-related benefits, and establishes a link between dissonant
14 ties and performance. Subsequently, it provides an in-depth analysis of employees' willingness
15 to rely on this potentially unpleasant but instrumental networking behavior, and suggests that
16 formal hierarchical rank, tenure, and unit membership as critical elements of the organizational
17 architecture drive dissonant tie formation. In the empirical analysis, the study utilizes survey and
18 interview data collected from engineers in a large manufacturing firm. The findings confirm that
19 seeking problem-solving assistance from difficult colleagues entails performance benefits.
20 Moreover, the embeddedness of individuals in the organizational architecture shapes the
21 employment of dissonant ties. Dissonant ties are, hence, context driven. By simultaneously
22 addressing the consequences and the drivers of employees' networking behavior, the study
23 presents a comprehensive theory of dissonant ties that challenges and refines previous research
24 on the interplay between positive and negative networks.

30 *Some older chaps like [name] and I, we're reputed to be difficult people. But really only*
31 *because it's our attitude to it all. We're combative... That's almost aggressiveness in*
32 *modern engineering... You have to take a sort of pseudo-aggressive mode and not just*
33 *give them the answer to a problem. That's not the game that we play. We challenge them*
34 *to reflect on their decisions and assumptions... And so we're difficult to get along with*
35 *because we just won't tell them what to do.*
36

37 *Interview with long tenured engineer*

38
39 *Most of the people that are difficult to work with tend to be people that work very*
40 *hard... They are very bright and think quicker than the rest of us. They can see the issue*
41 *and they don't understand why you don't see the issue... So, if you can channel the*
42 *awkwardness but get the output from them, they can actually make you look good. I've*
43 *got a guy I work with... and he's an incredibly hard worker, but he's very self-*
44 *opinionated, which a lot of people find very difficult to deal with. I just swear at him and*
45 *tell him where to go, but I get a huge amount of work out of him. It makes me look really*
46 *good. So I'm prepared to put up with that.*
47

48 *Interview with engineer*

49
50 According to social ledger theory (Labianca & Brass, 2006), networks of positive ties and
51 networks of negative ties co-exist in the workplace. Comparable to the two sides of the financial
52 ledger, employees derive benefits from networks of positive professional or personal ties, such as
53
54
55
56
57
58
59
60

1
2
3 advice seeking, knowledge transfer, or friendship, (e.g., Cross & Cummings, 2004; Sparrowe,
4 Liden, Wayne, & Kraimer, 2001). Conversely, negative tie networks, which may include dislike,
5
6 avoidance, or difficult working relationships, result in liabilities and have negative implications
7
8 for those involved (e.g., Baldwin, Bedell, & Johnson, 1997; Schulte, Cohen, & Klein, 2012).
9
10 Based on this duality, social ledger theory emphasizes the importance of jointly investigating
11
12 positive and negative networks and, thereby, comprehensively capture organizational reality
13
14 (Labianca & Brass, 2006). However, social ledger theory implicitly assumes that an employee's
15
16 positive and negative network ties are mutually exclusive and not directed at the same
17
18 individuals. Accordingly, many studies that jointly examine positive and negative ties in the
19
20 workplace regard them as two ends of a continuum: friends versus foes (e.g., Sherf &
21
22 Venkataramani, 2015), supportive versus antagonistic (Chiaburu & Harrison, 2008), or
23
24 energizing versus de-energizing (e.g., Parker, Gerbasi, & Porath, 2013).
25
26
27
28
29

30
31 In this study, I demonstrate that this assumption is short-sighted, as two employees may
32
33 simultaneously be connected by positive and negative network ties. Indeed, recent research on
34
35 workplace relationships proposes that individuals may be friends with their competitors (Ingram
36
37 & Roberts, 2000), "frenemies" connected by ambivalent relationships (Melwani & Rothman,
38
39 2015; Methot, Melwani, & Rothman, 2017), or colleagues who seek advice from each other even
40
41 if their relationship is conflictual (Marineau, Hood, & Labianca, 2018). This overlap of positive
42
43 and negative ties can be seen as a specific form of network multiplexity—the co-existence of
44
45 multiple types of network ties between two individuals (Kilduff & Brass, 2010).
46
47
48

49 In line with the opening quotes, this study conceptualizes the multiplexity of positive and
50
51 negative ties in terms of individuals seeking problem-solving assistance from colleagues with
52
53 whom they find it difficult to work. Problem-solving networks consist of professional network
54
55
56
57
58
59
60

1
2
3 ties, which serve as conduits of task-relevant knowledge and support (Casciaro, Gino, &
4 Kouchaki, 2014; Shah, Cross, & Levin, 2018). They are particularly important for knowledge-
5 intensive work (Hargadon & Bechky, 2006). The decision to turn to someone for problem-
6 solving assistance reflects a cognition-based positive evaluation of that person (Nebus, 2006). In
7 contrast, difficult working relationships are negative network ties (e.g., Merluzzi, 2017; Schulte
8 et al., 2012). They signal a cognition-based negative evaluation of colleagues based on their
9 perceived quality as co-workers (Labianca & Brass, 2006); as exemplified in the opening quotes,
10 working with those colleagues can be seen as challenging or awkward, for instance, because they
11 appear belligerent or arrogant. Problem-solving and difficult ties can overlap, as individuals may
12 turn to others with whom they have difficult working relationships for problem-solving
13 assistance. Borrowing from cognitive dissonance theory (Festinger, 1957), I introduce the term
14 “dissonant tie” to describe this positive-negative multiplexity characterized by an individual’s
15 conflicting cognitions of another person.

33 I argue that individuals engaged in knowledge-intensive work employ dissonant ties as an
34 instrumental networking behavior in anticipation of distinct work-related benefits. To show that
35 this anticipation is justified and to establish dissonant ties as a construct with significant
36 theoretical and practical implications, I first demonstrate that seeking problem-solving assistance
37 from difficult colleagues benefits the performance of the assistance seeker. The paper’s main
38 goal is to subsequently uncover the conditions under which individuals rely on this potentially
39 unpleasant but instrumental form of social networking. To this end, I integrate cost-benefit
40 theorizing (Borgatti & Cross, 2003; Nebus, 2006) with research on the importance of the
41 organizational context for network tie formation (e.g., Blau, 1955; Lincoln & Miller, 1979;
42 McEvily, Soda, & Tortoriello, 2014). In particular, elements of the organizational architecture
43
44
45
46
47
48

57
58
59
60

1
2
3 have repeatedly been shown to influence positive and negative tie networks (e.g., Kleinbaum,
4 Stuart, & Tushman, 2013; Merluzzi, 2017; Oh, Labianca, & Chung, 2006; Soda & Zaheer,
5
6 2012). I suggest that formal hierarchical rank, tenure, and unit membership as critical
7
8 architectural elements determine the benefits and costs individuals anticipate when seeking
9
10 problem-solving assistance from difficult colleagues. Thereby, these elements drive dissonant tie
11
12 formation in the workplace.
13
14
15

16
17 The study contributes to the literature on intraorganizational networks by developing and
18
19 testing a comprehensive theory of dissonant ties in knowledge-intensive workplaces. Following a
20
21 call by Ahuja, Soda, and Zaheer (2012), it moves beyond examinations of how the structural
22
23 characteristics of networks predict outcomes to investigate how individuals proactively employ
24
25 social networks to succeed at work. Focusing simultaneously on the consequences and drivers of
26
27 employees' purposeful networking behavior allows me to reveal ways in which individuals
28
29 secure resources that help them achieve task-related goals. As such, this study sheds light on the
30
31 agentic nature of individual behavior, and adds to the nascent stream of research on instrumental
32
33 networking employed in anticipation of task and professional benefits (e.g., Casciaro et al., 2014;
34
35 Marineau et al., 2018; Soda, Tortoriello, & Iorio, 2018).
36
37
38
39

40 By merging assumptions of social ledger theory with a network multiplexity perspective,
41
42 the study extends current knowledge on the interplay of positive and negative networks. First,
43
44 positive network ties have generally been linked to positive performance implications and
45
46 negative networks have been shown to entail negative consequences (e.g., Baldwin et al., 1997;
47
48 Labianca & Brass, 2006; Sparrowe et al., 2001; for notable exceptions, see Marineau, Labianca,
49
50 & Kane, 2016; Venkataramani, Labianca, & Grosser, 2013). However, the ways in which the
51
52 multiplexity of positive and negative ties (i.e., dissonant ties) influence outcomes have yet to be
53
54
55
56
57
58
59
60

1
2
3 established. Social ledger theory suggests that the consequences of positive and negative ties
4 counterbalance each other. Shifting the accounting logic inherent in social ledger theory towards
5 a synergistic understanding, I propose that this is not the case when the two types of ties overlap.
6
7 Instead, multiplex positive-negative ties exert a unique influence on performance. Second, by
8
9 examining elements of the organizational architecture as drivers of dissonant tie formation, I am
10
11 able to clarify conflicting findings in previous organizational network research. Casciaro and
12
13 Lobo (2008) illustrate that individuals avoid seeking assistance from colleagues they dislike. In
14
15 contrast, Ingram and Roberts (2000) and Marineau et al. (2018) provide evidence that positive
16
17 and negative ties can overlap. In highlighting the conditions under which individuals are willing
18
19 to seek problem-solving assistance from difficult colleagues, this study demonstrates that the
20
21 interplay of positive and negative intraorganizational networks and their convergence into
22
23 multiplexity are context driven.
24
25
26
27
28
29

30
31 In the empirical analysis, I use a mixed-method approach, which is considered most
32
33 suitable when introducing a new construct and linking it to established research (Edmondson &
34
35 McManus, 2007). I rely on quantitative survey data collected from the engineering department of
36
37 a large manufacturing firm, and apply regression analyses to uncover the performance
38
39 consequences of dissonant ties. I then utilize exponential random graph modeling (ERGM, e.g.,
40
41 Lusher, Koskinen, & Robins, 2013) to investigate the factors that drive individuals to seek
42
43 problem-solving assistance from difficult colleagues. EGRM allows estimating the likelihood of
44
45 observing problem-solving and difficult ties—separately and overlapping as dissonant ties—and
46
47 translates my theoretical arguments on the interplay of positive and negative tie formation into an
48
49 appropriate statistical representation. At the same time, I build on a series of qualitative
50
51
52
53
54
55
56
57
58
59
60

1
2
3 interviews with survey participants to substantiate the theoretical mechanisms behind the
4
5 consequences and drivers of dissonant ties.
6

7 8 **THEORY AND HYPOTHESES**

9 **Dissonant Ties in Intraorganizational Networks**

11 The positive component of dissonant ties, the problem-solving tie, can be characterized as
12
13 a professional network tie (Casciaro et al., 2014). Professional ties allow colleagues to exchange
14
15 work-related resources and support, and to engage in joint action. They are task-oriented and
16
17 cognition-based, but typically lack affect (Umphress, Labianca, Brass, Kass, & Scholten, 2003;
18
19 Varella, Javidan, & Waldman, 2012). In contrast, personal network ties, such as friendship, are
20
21 affect-based (Casciaro et al., 2014; Ibarra, 1993; Lincoln & Miller, 1979). Professional ties are
22
23 positive as they reflect a favorable evaluation of another's potential to help with work-related
24
25 problems or opportunities (Cross & Borgatti, 2004). From a value-added perspective, they are
26
27 created "as a result of cognitively coalescing previous experiences, social cues, observations, and
28
29 perceptions of the potential contact into an overall judgment" (Nebus, 2006: 628).
30
31
32
33

34 Problem-solving ties combine the knowledge and ideas of different individuals, and add
35
36 instrumental value for individuals and organizations (Rodan & Galunic, 2004; Shah et al., 2018).
37
38 As a form of instrumental networking (Casciaro et al., 2014), seeking problem-solving assistance
39
40 is not necessarily bound to the assistance seeker's or the provider's technical expertise, nor is it
41
42 part of their formal role requirements (Cross & Sproull, 2004). Hence, problem-solving ties can
43
44 be characterized as informal network ties (Venkataramani & Dalal, 2007) that are deliberately
45
46 created in anticipation of task and professional benefits (Casciaro et al., 2014). Unlike other
47
48 forms of task-related help-seeking, such as requesting advice or feedback (e.g., Hofmann, Grant,
49
50 & Lei, 2009; Mueller & Kamdar, 2011), problem-solving ties concern non-routine aspects of
51
52 work (Casciaro & Lobo, 2008). They usually involve intense dialogue and high levels of
53
54
55
56
57
58
59
60

1
2
3 cognitive engagement (Cross & Sproull, 2004), which enables learning and mutual development
4
5 (Shah et al., 2018). As seeking problem-solving assistance allows employees to deal with
6
7 complex tasks, it is an inherent part of knowledge-intensive work (Hargadon & Bechky, 2006).
8
9

10 The second component of dissonant ties—difficult working relationships—is a specific
11
12 type of negative network tie. Negative ties have been defined as interpersonal attitudes that
13
14 “represent an enduring, recurring set of negative judgments, feelings, and behavioral intentions
15
16 toward another person—a negative person schema” (Labianca & Brass, 2006: 597; italicized in
17
18 the original). They often involve conflict, jealousy, or rejection (Methot et al., 2017), and have
19
20 detrimental work-related consequences (e.g., Baldwin et al., 1997; Sparrowe et al., 2001;
21
22 Venkataramani et al., 2013). Similar to positive network ties, there are different types of negative
23
24 ties. As highlighted by Labianca and Brass (2006) and Labianca (2014), they may be affective
25
26 (e.g., dislike; Casciaro & Lobo, 2008); behavioral (e.g., avoidance; Venkataramani et al., 2013);
27
28 or cognitive (e.g., finding colleagues difficult to work with; Klein, Lim, Saltz, & Mayer, 2004;
29
30 Merluzzi, 2017; Schulte et al., 2012).
31
32
33
34

35 In line with this study’s focus on problem-solving ties founded on cognition-based
36
37 positive person evaluations, I examine difficult working relationships as cognition-based
38
39 negative ties (Labianca, 2014). Difficult ties reflect a cognition-based rather than affective
40
41 interpersonal attitude because the difficulty assessment concerns others’ perceived quality as co-
42
43 workers. Akin to positive, professional ties, they result from the cognitive coalescence of
44
45 experiences, cues, and observations of another individual into an overall judgement. In this case,
46
47 the judgement is negative because the perception of that individual’s work-related qualities is
48
49 unfavorable. Highlighted by the opening quotes, difficulty may refer to a range of qualities, such
50
51 as being challenging and playing devil’s advocate, coming across as aggressive, arrogant, and
52
53
54
55
56
57
58
59
60

1
2
3 self-opinionated, or being otherwise awkward to deal with. Different priorities, interpersonal
4 differences, and being perceived as hindering may also contribute to the emergence of difficult
5 ties (e.g., Hardavella, Saad, & Bjerg, 2015; Klein et al., 2004; Schulte et al., 2012; Sparrowe et
6 al., 2001).
7
8
9
10

11
12 Problem-solving and difficult network ties share common ground, as both evoke certain
13 cognitive schemas regarding other persons' work-related qualities (Fiske & Taylor, 2008),
14 thereby influencing individuals' behaviors toward them (e.g., Sherf & Venkataramani, 2015;
15 Venkataramani & Dalal, 2007). At the same time, the evoked cognitions conflict: favorable
16 evaluations of another person's problem-solving capacity draw individuals towards that person
17 while finding someone difficult keeps individuals away from that person. Nevertheless, the two
18 types of ties may overlap. Borrowing from cognitive dissonance theory (Festinger, 1957), I use
19 the term "dissonant tie" to describe multiplexity of problem-solving and difficult ties. I define
20 dissonant ties as the overlap of network ties characterized by an individual's conflicting
21 cognitions of another person. Hence, dissonant ties comprise associative and dissociative forces.
22
23 In line with cognitive dissonance theory, their formation can be seen as counter-attitudinal
24 behavior, which occurs when individuals act in conflict with their cognitive attitudes (Hinojosa,
25 Gardner, Walker, Cogliser, & Gullifor, 2017). Dissonant tie formation involves agency. Building
26 on a recent conceptualization of instrumental networking (Casciaro et al., 2014), it reflects
27 individuals' conscious and purposeful engagement in counter-attitudinal behavior in anticipation
28 of task and professional benefits.
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 Just like their positive and negative components, dissonant ties are based on cognition.
50 More specifically, they are characterized by tie-inherent cognitive inconsistency. Like all
51 cognition-based ties, they may be intertwined with affect (Casciaro & Lobo, 2015; Lawler, 2001)
52
53
54
55
56
57
58
59
60

1
2
3 and, for instance, give rise to feelings of discomfort (Hinojosa et al., 2017). However, attitudinal
4
5 judgements and their behavioral consequences can also operate on a purely cognitive basis
6
7 (Eagly & Chaiken, 1998). Accordingly, the employment of cognition-based positive-negative
8
9 ties as a form of instrumental networking behavior, rather than their affective effects, will be the
10
11 main focus of this research. Moreover, dissonant ties are conceptually related to but distinct from
12
13 relational ambivalence, which has recently attracted the attention of management scholars
14
15 (Rothman, Pratt, Rees, & Vogus, 2017). Defined as “the simultaneous experience of positive and
16
17 negative emotional or cognitive orientations toward a person, situation, object, task, goal, or
18
19 idea” (Rothman et al., 2017: 33), ambivalence has been argued to be void of any behavioral
20
21 component (Ashforth, Rogers, Pratt, & Pradies, 2014)—such as the formation of network ties. In
22
23 other words, the assumption that individuals consciously seek ambivalence is inconsistent with
24
25 existing views, while the literature on dissonance explicitly allows for individuals’ engagement
26
27 in counter-attitudinal behavior to achieve desired outcomes (Hinojosa et al., 2017).
28
29
30
31
32

33 Given the inherent tension between positive and negative cognitions in dissonant ties,
34
35 under which conditions are individuals willing to adopt this counter-attitudinal behavior by
36
37 seeking problem-solving assistance from difficult colleagues? To answer this question, I first
38
39 argue that dissonant ties positively affect the performance of assistance seekers. Thereby, I show
40
41 that individuals’ anticipation of benefits from dissonant ties is actually justified. In proposing
42
43 that dissonant ties are antecedents of performance, I follow the vast majority of theoretical (e.g.,
44
45 Labianca & Brass, 2006) and empirical (e.g., Balkundi & Harrison, 2006) research on the
46
47 network-performance relationship in organizational settings. The underlying assumption is that
48
49 network ties, in this case dissonant ties, serve as conduits for benefits or liabilities that influence
50
51 employees’ abilities to get things done (Ibarra, 1993). Second, I undertake an in-depth analysis
52
53
54
55
56
57
58
59
60

1
2
3 of the employment patterns of dissonant ties, investigating the drivers of cognition-based
4
5 positive-negative tie formation as a form of instrumental networking behavior. In line with the
6
7 cognitive conceptualization of dissonant ties, I argue that their formation follows a cost-benefit
8
9 evaluation (Borgatti & Cross, 2003; Nebus, 2006), which is driven by elements of the
10
11 organizational architecture. The conceptual framework, which integrates the consequences and
12
13 drivers of dissonant ties, is summarized in Figure 1.
14
15

16
17 --- Insert Figure 1 about here ---
18

19 **Performance Consequences of Dissonant Ties**

20
21 In knowledge-intensive work, performance is largely a product of solving complex, ill-
22
23 structured tasks with multiple possible solutions and solution paths by applying creativity and
24
25 analytical thinking (Alvesson, 2004; Cross & Cummings, 2004; Vincenti, 1990). Effective
26
27 employees are able to work out a solution for a given task despite numerous constraints related to
28
29 the task itself (e.g., the amount of time and money available) or its outcomes (e.g., costs, product
30
31 features, or service features) (Sheppard, Colby, Macatangay, & Sullivan, 2007; Stokes, 2014).
32
33 To arrive at a solution, employees in knowledge-intensive workplaces habitually seek assistance
34
35 via professional network ties. Problem-solving interactions in which assistance providers offer
36
37 constructive criticism and prompt new perspectives (Hargadon & Bechky, 2006; Shah et al.,
38
39 2018) enhance assistance seekers' abilities to generate solutions to the complex tasks they face
40
41 (e.g., Rodan & Galunic, 2004). In line with social ledger theory, these positive networks, hence,
42
43 entail performance benefits. In contrast, difficult ties, as negative network relationships, result in
44
45 liabilities, such as reduced perceived psychological safety (Schulte et al., 2012) and negative
46
47 impacts on performance (Baldwin et al., 1997).
48
49
50
51
52

53 The performance consequences of positive-negative tie multiplexity have not previously
54
55 been examined. Social ledger theory assumes an additive interplay of the consequences of
56
57
58
59
60

1
2
3 positive and negative networks. That is, the benefits and costs that the two types of ties entail
4 counterbalance each other. This logic would suggest that dissonant ties have a neutral effect on
5 performance. However, merging social ledger theory with a network multiplexity perspective,
6 this assumption may no longer hold. Overlapping as dissonant ties, positive and negative
7 network ties may bring about consequences that differ from neutrality. Suggesting a synergistic
8 interplay, I argue that seeking problem-solving assistance from difficult colleagues gives rise to
9 three distinct benefits that promote performance in knowledge-intensive work.
10
11
12
13
14
15
16
17
18

19 First, the employment of dissonant ties as networking behavior provides access to unique
20 resources. Specifically, it allows sourcing and benefiting from rare problem-solving capabilities
21 or knowledge not extensively used within an organization as a reputation of being difficult to
22 work with dissuades the majority of employees from approaching a colleague. This assumption
23 is in line with findings on individuals' help-seeking preferences—individuals typically target
24 others who are accessible and with whom it is easy to interact (e.g., Borgatti & Cross, 2003;
25 Hofmann et al., 2009). It is also consistent with the finding that employees often concur on
26 which colleagues they find difficult (Robins, Pattison, & Wang, 2009). By risking to approach a
27 difficult person, investing the time and mental resources needed to cope with potential distress
28 (Denham, Ackers, & Travers, 1997; Melwani & Rothman, 2015), or, put simply, being “prepared
29 to put up with that” (opening quote #2), assistance seekers relying on dissonant ties gain a
30 competitive advantage. Accessing capabilities and knowledge not extensively used by their
31 colleagues and combining them with their own knowledge, they can increase the likelihood of
32 constructing viable solutions to their complex tasks (Hargadon & Bechky, 2006).
33
34
35

38
39
40
41
42
43
44
45
46
47
48
49
50

51 The performance benefits of dissonant ties do, however, not depend on colleagues being
52 widely regarded as difficult. Dissonant ties can also be idiosyncratic, resulting from interpersonal
53
54
55
56
57
58
59
60

1
2
3 differences (Robins et al., 2009) and can still promote performance. A second rationale for
4 employees involved in knowledge-intensive work to consciously seek problem-solving
5 assistance from difficult colleagues lies in the desire to have their assumptions challenged. As
6 described in the opening quotes, difficult working relationships can be triggered by individuals
7 questioning others' decisions and assumptions or presenting opposing opinions. Hence, dissonant
8 ties imply confrontation with disagreement, dissenting viewpoints, and diverse perspectives that
9 assistance seekers have not previously considered. These factors have been linked to divergent
10 thinking and an expansion of focus (e.g., Nemeth, 1995; Nemeth & Kwan, 1987), which are
11 critical for knowledge-intensive work (Alvesson, 2004). They may lead to reflective reframing
12 (Hargadon & Bechky, 2006), a shift in the conception of a given problem, and the uncovering of
13 novel connections, thereby allowing for alternative recognition and enhanced solution
14 generation. Evidence of individuals deliberately employing such networking behavior to succeed
15 at work is provided by Marineau et al. (2018), who demonstrate that employees seek advice from
16 colleagues with whom they have task conflicts, presumably to prevent groupthink (Janis, 1972).
17 Establishing the link to performance, research on devil's advocacy and dialectical inquiry
18 suggests that intentional use of such strategies leads to superior outcomes (Schweiger, Sandberg,
19 & Rechner, 1989).

20
21

36
37
38
39
40
41
42 The two arguments outlined above explicitly build on the conceptualization of dissonant
43 tie formation as a form of instrumental networking—employees consciously seek problem-
44 solving assistance from difficult colleagues anticipating access to unique resources and challenge
45 of their assumptions. While they do not necessarily drive individuals' networking behavior,
46 unintended cognitive processes may additionally play a role in the influence of dissonant ties on
47 performance. Dissonant ties are characterized by cognitive inconsistency, which may give rise to
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 distress or perceived unpleasantness (Festinger, 1957). This may be distracting and shift attention
4 away from jointly generating problem solutions to engaging in coping strategies (Denham et al.,
5 1997; Hinojosa et al., 2017); yet, several studies provide evidence that perceived inconsistencies
6 may actually promote performance. Research on their cognitive consequences has linked
7 dissonance and controversy to enhanced cognitive activity, creativity, and performance (e.g., De
8 Dreu & De Vries, 1997; Harmon-Jones, 2012; Schulz-Hardt, Mojzisch, & Vogelgesang, 2007).
9 Dissonant attitudes increase the intensity of information processing (Rydell, McConnell, &
10 Mackie, 2008; Schulz-Hardt et al., 2007), while controversy leads individuals to find more novel
11 solutions (De Dreu & De Vries, 1997; Nemeth & Kwan, 1987). The tension between positive
12 and negative cognitions experienced when approaching difficult colleagues for assistance may,
13 hence, function as a cognitive catalyst in employees' search for solutions to complex tasks. All
14 three mechanisms—access to unique resources, challenge of assumptions, and cognitive
15 catalysis—involve a synergistic rather than additive interplay of cognition-based positive-
16 negative tie multiplexity and suggest:

36 *their performance.*
37

38 **Drivers of Dissonant Tie Formation in the Workplace**

39
40 In this section, I argue that employees consciously decide whether to seek problem-
41 solving assistance from difficult colleagues by weighing the distinct benefits associated with
42 dissonant ties against their perceived costs. Specifically, in line with the conceptualization of
43 dissonant ties as based on cognitions, I build upon a cognitive-consequentialist approach to
44 instrumental networking behavior centered on cost-benefit evaluations (Borgatti & Cross, 2003;
45 Nebus, 2006). This approach matches the accounting logic inherent in social ledger theory. At
46 the same time, by bringing in positive-negative tie multiplexity, I again move beyond a key
47
48

54
55
56
57
58
59
60

1
2
3 assumption of social ledger theory, namely that the benefits of positive ties are compared to the
4 costs of negative ties. I reason that employees assess dissonant ties as a whole by comparing the
5 benefits of the combined positive-negative ties to their combined costs. As I outline in detail
6 below, they weigh the benefits of access to unique resources and challenge of assumptions
7 against potential unpleasantness resulting from tie-inherent cognitive inconsistency and practical
8 risks associated with approaching a difficult colleague. Similar to mere problem-solving and
9 difficult ties, dissonant tie formation is, hence, based on the cognitive coalescence of
10 experiences, perceptions, cues, and observations of another individual—which in this case are
11 simultaneously positive and negative—into an overall cost-benefit judgement.
12
13

19
20
21
22
23

24 As a critical aspect determining the net benefits an employee will associate with
25 dissonant ties and, thus, a critical driver of dissonant tie formation, I draw attention to the
26 organizational context, which has long been argued to shape work-related cognitions and
27 behaviors (e.g., Elsbach, Barr, & Hargadon, 2005; March & Simon, 1958; Simon, 1990),
28 including networking behavior (e.g., Blau, 1955; Lincoln & Miller, 1979; McEvily et al., 2014).
29 Suggesting that the interplay of positive and negative intraorganizational networks is context
30 driven, I investigate employees' formal hierarchical rank, tenure, and unit membership as
31 contextual elements that define their embeddedness in the organizational architecture. These
32 contextual elements specify roles, responsibilities, resource endowments, and authority levels
33 (Galbraith, 1973; March & Simon, 1958), and they create intraorganizational boundaries, thereby
34 providing a basis for self-categorization (Hogg & Terry, 2000; Turner, 1987). As such, they
35 influence which benefits and costs employees associate with specific types of network ties.
36 Accordingly, they have repeatedly been highlighted as important determinants of positive and

3 negative tie formation (e.g., Kleinbaum et al., 2013; Labianca, Brass, & Gray, 1998; McEvily et
4 al., 2014; Merluzzi, 2017; Oh et al., 2006; Soda & Zaheer, 2012; Srivastava & Banaji, 2011).
5
6

7
8 Formal hierarchical rank creates a vertical organizational boundary accompanied by
9
10 power differentials, which are reflected in the unequal distribution of resources, responsibilities,
11 and decision-making rights. High-ranking employees have more formal power and authority than
12 low-ranking employees; they typically control the allocation of means, rewards, and punishments
13 (French & Raven, 1959), influence promotion decisions and have superior access to resources
14 (March & Simon, 1958), and are able to provide administrative support (Ibarra, 1993). In
15 contrast, tenure is not part of the formal organizational structure, and it is not associated with
16 formal power and access to resources. However, differences in tenure also create a vertical
17 boundary between employees, as longer tenure is associated with greater experience and more
18 tacit knowledge about the organization (Becker, 1964), higher levels of expert power (French &
19 Raven, 1959), and the potential ability to provide superior technical and task-related support
20 (Ibarra, 1993). Although some organizations consider tenure a criterion for promotion, it is not
21 necessarily related to formal hierarchical rank (Ng & Feldman, 2010). Particularly in knowledge-
22 intensive workplaces, high-ranking positions that comprise leadership responsibilities are
23 increasingly staffed with external hires (Royal & Althausser, 2003); at the same time, longer
24 tenured knowledge workers are often less interested in taking on leadership roles and instead
25 pursue expert careers (Allen & Katz, 1986; Brousseau, Driver, Kristina, & Larsson, 1996). In
26 addition to formal hierarchical rank and tenure, I consider employees' membership in discrete
27 units, such as divisions, functions, or work teams. Unit membership creates horizontal
28 boundaries in the organization, and the antecedents and consequences of network ties spanning
29 these boundaries are among the most popular topics in organizational network research (e.g.,
30

2
3 Kleinbaum et al., 2013; Lomi, Lusher, Pattison, & Robins, 2014). Due to their different resource
4 implications (e.g., formal or expert power) and ways of structuring the organization (e.g., vertical
5 or horizontal boundaries), formal hierarchical rank, tenure, and unit membership are assumed to
6 exert unique influences on evaluations of the benefits and costs associated with network ties and,
7 hence, affect tie formation.
8
9

10
11
12
13
14
15 To provide a comprehensive picture of how the different elements of the organizational
16 architecture drive dissonant ties, I follow Cross and Sproull (2004) in considering tie formation
17 from three perspectives: ego, alter, and dyad. The *ego perspective* focuses on the individual (the
18 “ego”) proactively engaging in instrumental networking. Previous research shows that low-
19 ranking and shorter tenured egos are particularly likely to seek advice and information (e.g.,
20 Lazega, Mounier, Snijders, & Tubaro, 2012; Lomi et al., 2014), but not necessarily problem-
21 solving assistance (Cross & Sproull, 2004). Moreover, formal hierarchical rank is positively
22 related to egos finding colleagues difficult (Merluzzi, 2017). In this study, the ego perspective
23 sheds light on how egos’ embeddedness in the organizational architecture affects their evaluation
24 of the benefits and costs of dissonant tie formation and, thereby, influences the propensity to
25 seek problem-solving assistance from difficult colleagues—irrespective of the organizational
26 embeddedness of those colleagues.
27

29
30
31
32
33
34
35
36
37
38
39
40
41

42 The latter is attended to from the *alter perspective* describing the relationship between
43 alters’ embeddedness in the organizational architecture and their being approached with
44 dissonant ties. Prior research demonstrates that high-ranking and longer tenured alters are
45 typically sought-after and valued advisors (e.g., Lazega et al., 2012; Lincoln & Miller, 1979).
46 High-ranking employees can offer administrative guidance and authoritative legitimacy, and
47 longer tenured colleagues often possess superior subject-matter expertise, experience, and expert
48

54
55
56
57
58
59
60

1
2
3 legitimacy (Becker, 1964; Ibarra, 1993). At the same time, high-ranking and longer tenured
4
5 colleagues are more likely to be perceived as difficult due to the vertical boundaries and the
6
7 associated power differences that separate them from their colleagues.
8
9

10 Finally, the *dyad perspective* refers to the two parties—the individual employing the
11
12 dissonant tie and the difficult assistance provider—as a unit. It allows adding a unique focus on
13
14 boundary spanning to the analysis, examining whether dissonant tie formation is more likely
15
16 within or across vertical and horizontal boundaries in the organizational architecture. Prior
17
18 research raises opposing expectations regarding the role of such boundaries for positive and
19
20 negative tie formation. The principle of homophily proposes that individuals form positive
21
22 network ties with similar others (McPherson, Smith-Lovin, & Cook, 2001); hence, within, rather
23
24 than across, boundaries. At the same time, arguments that support a positive relationship between
25
26 similarity and positive network ties imply a negative relationship between similarity and negative
27
28 ties. Mechanisms such as similarity-attraction and in-group favoritism (Byrne, 1971; Turner,
29
30 1987), which lead to positive tie homophily, as flipside suggest the formation of negative ties
31
32 among employees with dissimilar formal hierarchical rank, tenure, or unit membership and,
33
34 hence, across vertical and horizontal boundaries. This raises the question of how boundaries
35
36 influence the interplay of positive and negative network ties and drive dissonant tie formation.
37
38
39
40
41

42 Table 1 summarizes the distinctions among ego, alter, and dyad that guide my subsequent
43
44 theorizing on the drivers of dissonant tie formation. It demonstrates that formal hierarchical rank
45
46 and tenure relate to all three perspectives. In contrast, unit membership does not comprise
47
48 hierarchical ordering and does, therefore, not affect ego and alter independently. Reflecting
49
50 horizontal differentiation, it only concerns the dyad, as network ties may either occur between
51
52 employees with the same or with different unit membership.
53
54
55
56
57
58
59
60

1

3
4 --- Insert Table 1 about here ---

5 ***The ego perspective.*** The ego perspective explains how employees' formal hierarchical
6 rank and tenure influence their propensity to purposefully employ dissonant ties. Building on the
7 cost-benefit logic, I argue that while high-ranking and longer tenured employees may be more
8 inclined to find colleagues difficult (Merluzzi, 2017), low-ranking and shorter tenured employees
9 are more likely to seek problem-solving assistance from those colleagues they find difficult.
10 First, due to their inferior formal hierarchical and informal tenure-based power credentials, these
11 employees should assign a comparatively high value to the benefits associated with problem-
12 solving assistance from difficult colleagues, namely access to unique resources and challenge of
13 assumptions. To gain these benefits and thereby potentially improve their standing in the
14 organization, these employees should be more willing to jump through the proverbial hoops
15 (Super, 1980) by employing dissonant ties at work. In support of this claim, psychological
16 research on age, which is typically closely correlated with tenure (Ng & Feldman, 2010, 2013),
17 reveals that younger employees demonstrate stronger orientations towards growth (Ebner,
18 Freund, & Baltes, 2006; Freund, 2006). The knowledge intensity of the workplace further fuels
19 the assumption—access to unique assistance providers and divergent thinking can foster
20 complex problem solving and norms demand that low-ranking and shorter tenured employees
21 speak up to ensure task success rather than keep their heads down (Cross & Parker, 2004).

31
32
33
34
35
36
37
38
39
40
41
42
43

44 Second, low-ranking and shorter tenured employees may be more willing to tolerate
45 cognitive inconsistency and practical risks, such as interpersonal complications, associated with
46 dissonant ties and, therefore, associate fewer costs with their formation. With regards to formal
47 hierarchical rank, psychological research provides evidence of a negative relationship with
48 individuals' risk-taking proclivity (Du Brin, 1988). When transposed to the employment of
49 dissonant ties, low-ranking employees may be more willing than their high-ranking colleagues to
50
51
52
53
54
55
56
57
58
59
60

1
2
3 “risk” the investment of time and mental resources necessary for simultaneously positive and
4 negative cognition-based ties. Similarly, scholars have established a negative relationship
5 between tenure and experimentation (Miller & Shamsie, 2001). Older, longer tenured employees
6 prioritize tasks that are emotionally satisfying (Carstensen, Isaacowitz, & Charles, 1999) and
7 match their personal interests (Beier & Ackerman, 2001), which indicates a preference for
8 cognitive consistency that is inconsistent with dissonant tie formation.
9

10
11 In conclusion, low-ranking and shorter tenured employees should emphasize the benefits
12 of dissonant ties to get ahead in the knowledge-intensive workplace, and they should tolerate tie-
13 inherent inconsistency and risks. Conversely, high-ranking and longer tenured employees should
14 associate net costs with dissonant tie formation and be less willing to endure counter-attitudinal
15 behavior for the purpose of professional goal attainment. These arguments lead to the following
16 hypotheses on ego’s embeddedness in the organizational architecture and the formation of
17 multiplex positive-negative ties in intraorganizational networks:
18

dissonant ties.

61
62
63
64
65
66
67
68
69
70
The alter perspective. Both an alter’s formal hierarchical rank and tenure should
positively affect the formation of problem-solving and difficult ties per se. However, the two
elements of the organizational architecture should function differently as drivers of positive-
negative tie multiplexity, that is, dissonant tie formation. Due to the different types of power and
support associated with formal hierarchical rank as compared to tenure the existence of a
difficult relationship should tip the balance from net benefits to net costs when employees seek
assistance from high-ranking alters but not when they seek assistance from longer tenured alters.

1
2
3 While dissonant ties with high-ranking colleagues may yield work-related benefits, such
4 as dissonant tie-specific benefits as well as access to resources and administrative support, their
5 formation should be perceived as disproportionately risky. Because of their authority and control
6 over the allocation of means, rewards, and punishments (French & Raven, 1959), high-ranking
7 employees, who are also difficult co-workers constitute a threat, rather than an asset, to the
8 assistance seeker. Their difficulty, for instance reflected in challenging or aggressive behavior,
9 makes them less predictable. As they influence promotion decisions, interactions with them have
10 the potential to produce negative career effects and other work-related costs. Given that
11 individuals wish to avoid complications with hierarchical superiors (Bolino, Kacmar, Turnley, &
12 Gilstrap, 2008), these risks should carry substantial weight in the cost-benefit evaluation. In fact,
13 they should outweigh the added value of this form of instrumental networking, thereby leading
14 employees to avoid approaching high-ranking colleagues with problem-solving requests if they
15 simultaneously perceive those colleagues as difficult.
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32

33 The same risks are not associated with dissonant ties with longer tenured alters, as they
34 do not possess high levels of formal power and control over rewards and punishment. Instead,
35 tenure is positively related to task experience and expert power (Becker, 1964; Ibarra, 1993) of
36 foremost importance for knowledge-intensive work. Thus, when approaching longer tenured,
37 difficult alters for problem-solving assistance, individuals can not only reap dissonant tie-specific
38 benefits—access to unique resources and challenge of their assumptions. In addition, they can
39 obtain benefits owing to these colleagues' superior knowledge and experience. Thus,
40 approaching longer tenured alters with dissonant ties is doubly beneficial for knowledge-
41 intensive work, which should outweigh the tie-inherent costs.
42

60

1
2
3 Overall, the distinction between power over rewards and punishments associated with
4 formal hierarchical rank as opposed to task experience and expert power associated with tenure
5 is critical for the benefits and practical risks associated with problem-solving interactions with
6 difficult colleagues. It explains why, from the alter perspective, these two elements of the
7 organizational architecture should function differently as drivers of dissonant ties and we need to
8 account for both when attempting to understand the interplay of positive and negative
9 intraorganizational networks. I hypothesize:

10
11
12
13
14
15
16
17
18
19 *H3a: There is a negative relationship between alters' formal hierarchical rank and their*
20 *being approached with dissonant ties.*

21
22
23 *H3b: There is a positive relationship between alters' tenure and their being approached*
24 *with dissonant ties.*

25
26 ***The dyad perspective.*** The dyad perspective accounts for similarity in egos' and alters'
27 formal hierarchical rank, tenure, and unit membership, and allows for determining whether
28 network tie formation is more likely within or across vertical and horizontal boundaries in the
29 organizational architecture. As outlined above, prior theoretical and empirical evidence leads to
30 opposing expectations regarding boundaries as drivers of positive and negative network ties.
31 With respect to positive-negative multiplexity, I argue that the employment patterns of dissonant
32 ties differ for formal hierarchical rank and tenure as opposed to unit membership. While
33 seemingly counterintuitive, employees should establish dissonant ties within vertical boundaries
34 but across horizontal boundaries. The following comparison of the distinct benefits and costs of
35 dissonant ties in light of the three architectural elements will demonstrate why.
36
37
38
39
40
41
42
43
44
45
46
47
48

49 With regard to formal hierarchical rank, I suggest that although difficult ties may occur
50 more frequently between dissimilar employees, these ties are less likely to turn dissonant.
51
52 Instead, similarity of formal hierarchical rank should decrease the practical risks as well as the
53
54
55

1
2
3 perceived unpleasantness that egos associate with dissonant tie formation. First, the above-
4 mentioned risks of dissonant ties with high-ranking alters should weigh even higher for low-
5 ranking assistance seekers. Given their lack of formal power and authority, dissonant ties with
6 difficult alters of high formal rank should seem particularly daunting and, hence,
7 disproportionately costly. In contrast, similarity implies a balance of formal power and control
8 over rewards and punishments and mitigates the likelihood that negative career implications will
9 result from problem-solving interactions with difficult colleagues. Second, a similar formal
10 hierarchical rank establishes common ground, which is reflected in a shared language and similar
11 thought worlds (Dougherty, 1992). This common ground may attenuate perceived
12 unpleasantness resulting from the inconsistent cognitions inherent in dissonant ties, making it
13 easier for the assistance seeker to focus on their instrumental benefits. This argument suggests
14 that homophily as ubiquitous principle that guides human interaction (McPherson et al., 2001)
15 also influences dissonant tie formation.

16
17
18
19

21
22
23
24
25
26
27
28
29
30
31
32
33 A similar homophily-argument applies to tenure. Even if the above theorizing predicting
34 a negative effect of ego tenure and a positive effect of alter tenure on tie formation seems to
35 imply that dissonant ties are formed between dissimilar employees—directed from shorter
36 tenured to longer tenured individuals—this is not necessarily the case. The above perspectives
37 concern egos' and alters' involvement in dissonant ties irrespective of their counterparts' tenure.
38 Moreover, longer tenured individuals have no particular inducements to seek assistance from
39 lower tenured, difficult colleagues. Instead, shared experiences and a common language
40 developed among employees who entered the organization around the same time (Zenger &
41 Lawrence, 1989) provide commonality, which should make enduring counter-attitudinal
42 behavior for the purpose of professional goal attainment seem less costly for ego and, hence,
43

2
3 lower the hurdles for dissonant tie formation. My reasoning that homophily might attenuate the
4 unpleasantness associated with dissonant ties is in line with findings by Lazega et al. (2012),
5 who show that interpersonal similarity can lessen the hindering effects of various barriers to
6 seeking advice.
7
8
9
10

11
12 With regard to unit membership, I propose a different outcome of the cost-benefit
13 evaluation that determines dissonant tie formation. Unit membership diverges markedly from
14 formal hierarchical rank and tenure, as it creates horizontal rather than vertical boundaries.
15 Moreover, it structures the day-to-day organization of work—individuals in the same unit are
16 typically spatially co-located, collaborate closely, and meet one another frequently. Thus, even if
17 homophily triggered by joint unit membership attenuates the perceived unpleasantness caused by
18 cognitive inconsistency inherent in dissonant ties, the closeness that joint unit membership
19 creates makes dissonant tie formation disproportionately risky from a practical point of view.
20 Any complication from interactions with a difficult colleague could directly affect the workflow
21 of not only the involved ego and alter but also of other unit members. Conversely, boundary-
22 spanning ties are episodic and determined by nonrecurring tasks (Kleinbaum et al., 2013).
23 Hence, cross-unit dissonant ties are likely to involve targeted interactions with few negative
24 repercussions for the assistance seeker's day-to-day work. In other words, even if a problem-
25 solving interaction with a difficult colleague aggravates the negative component of a dissonant
26 tie, the unit boundary creates a safe distance between the involved parties, making it easier to
27 avoid each other in the future. Moreover, seeking assistance from difficult colleagues in other
28 units has the additional appeal of providing access to heterogeneous viewpoints and knowledge
29 unavailable in ego's own unit (e.g., Burt, 1992; Oh et al., 2006). These benefits complement

3 dissonant tie-specific benefits, such as access to unique resources and challenge of assumptions,
4 making boundary-spanning dissonant ties particularly valuable for knowledge-intensive work.
5
6

7
8 Based on the above arguments, I propose:
9

10 *H4a: There is a positive relationship between similarity in formal hierarchical rank and*
11 *dissonant tie formation between dyads.*
12

13 *H4b: There is a positive relationship between similarity in tenure and dissonant tie*
14 *formation between dyads.*
15

16
17 *H4c: There is a negative relationship between working in the same unit and dissonant tie*
18 *formation between dyads.*
19

20 **DATA AND METHODS**

21 **Research Design and Empirical Setting**

22
23 I use a combined quantitative and qualitative approach, as recommended for introducing
24 a new construct to the literature (Edmondson & McManus, 2007). I rely on a large-scale survey
25 to formally test my hypotheses through quantitative analyses, while qualitative interviews
26 provide greater insight into the mechanisms underlying the numerical results. This combination
27 of methods offers an in-depth understanding of the consequences and drivers of dissonant ties.
28
29
30
31
32
33

34 All data were collected from the engineering department of a large manufacturing firm
35 active in the aerospace industry in a developed economy as an exemplar of a highly knowledge-
36 intensive workplace. The aerospace industry builds on broad and sophisticated knowledge;
37 aerospace manufacturers construct complex, heterogeneous systems; and they rely on continuous
38 innovation to increase economic and technological returns (Sammorra & Biggiero, 2008). The
39 firm under study delivers specialized designs and produces complex, technical components as
40 part of an international supply chain. Its engineering department comprises 11 cross-functional
41

1
2
3 units, each with its own formal leader, and a general leadership unit.¹ The engineers engage in a
4
5 variety of complex tasks in design engineering and analysis. As is typical in aerospace
6
7 engineering as complex problem-solving activity (Vincenti, 1990), the engineers' day-to-day
8
9 work is laden with ambiguities, which frequently require them to make judgement calls
10
11 (Downer, 2011). At the same time, they need to deal with constraints imposed by deadlines and
12
13 cost-reduction targets, and meet strict aviation-safety requirements. Overall, the chosen setting is
14
15 comparable to other studies of engineers and technical professionals in knowledge-intensive
16
17 workplaces, such as Grodal, Nelson, and Siino (2015), Hargadon and Bechky (2006), and Perlow
18
19 (1999).
20
21
22

23 **Survey Data**

24
25 To collect the quantitative data, I conducted an online survey of members of the
26
27 engineering department in which I asked questions about their networks, individual
28
29 characteristics, and performance. The firm's management provided information on the engineers'
30
31 positions in the formal organization (i.e., formal hierarchical rank, unit membership, and
32
33 reporting lines). Of the 239 engineers invited to participate in the survey, 171 returned completed
34
35 questionnaires, representing a response rate of 72 percent. I compared respondents to non-
36
37 respondents in terms of the number of nominations received as: a provider of problem-solving
38
39 assistance, difficult to work with, an alter in dissonant ties, and a high-performing colleague. The
40
41 t-test results revealed no significant differences between respondents and non-respondents with
42
43 respect to these characteristics. All non-respondents were of low hierarchical rank, as defined
44
45
46
47
48
49
50
51

52 ¹ Members of the general leadership unit are high-ranking engineers, some of whom function as supervisors for
53 employees and unit leaders.
54
55
56
57
58
59
60

1
2
3 below. In line with common practice (e.g., Soda et al., 2018), ties to non-respondents were
4
5 excluded from the empirical analysis.
6

7
8 In the following, I describe the different types of quantitative data before explaining how
9
10 they were transformed into variables for investigating the consequences and drivers of dissonant
11
12 ties.
13

14
15 **Networks.** As recommended by Labianca and Brass (2006), I collected whole-network
16
17 data using the roster method. I captured *seeking problem-solving assistance* as the positive
18
19 network in my study by asking: “When you need to engage in creative problem-solving
20
21 regarding your job, who are the people you go to, to help you think outside of the box and
22
23 consider different aspects of the problem innovatively?” (Casciaro & Lobo, 2008). To capture
24
25 the negative network, I measured *difficult relationships* by asking: “Who do you find difficult to
26
27 work with?” (Schulte et al., 2012). Network data were collected as asymmetric and binary data
28
29 (i.e., a network tie from ego to alter is either present or absent).
30
31

32
33 **Performance.** To capture *individual performance*, I asked participants: “With respect to
34
35 the current position at work, who are the most effective people that you work with?” This
36
37 question was agreed upon with the firm’s management as a parsimonious way to identify
38
39 employees with exemplary in-role performance. As with problem solving and difficult network
40
41 ties, I provided respondents with a roster of all members of the engineering department and
42
43 collected binary data. For a similar approach using influence instead of effectiveness, see
44
45 Sparrowe and Liden (2005).
46
47

48
49 **Individual attributes.** The analyses consider *formal hierarchical rank*, which is a binary
50
51 variable distinguishing between high-ranking (1) and low-ranking (0) employees. Unit leaders
52
53 and members of the general leadership unit were coded as high-ranking employees. I account for
54
55
56
57
58
59
60

1
2
3 *tenure* in the organization measured in years. *Unit membership* is a categorical variable that
4 captures each individual's affiliation with one of the engineering units. *Level of education* is
5 measured on a scale from (1) high-school education to (4) Ph.D. Finally, I account for *gender*
6 with (1) being male and (0) female.
7
8
9

10
11
12 ***Dyadic attribute.*** When modeling the drivers of dissonant ties, I consider reporting lines
13 as dyadic *supervisor-supervisee relationships*. For this purpose, I use a dyadic network attribute
14 to capture whether an employee is the direct subordinate of another employee.
15
16
17

18 19 **Quantitative Analysis: Consequences of Dissonant Ties**

20
21 I transformed the effectiveness nominations each engineer could receive into two
22 performance variables. To achieve comparability with more traditional approaches to
23 performance evaluations, I first created a binary variable that captured whether an engineer was
24 nominated as particularly effective by their direct supervisor. Evaluations by one's supervisor are
25 the most common approach to measuring performance used in research and practice (see Arvey
26 & Murphy, 1998; Bretz, Milkovich, & Read, 1992; Mehra, Kilduff, & Brass, 2001). Second, I
27 counted the number of effectiveness nominations that each engineer received from formal
28 leaders (i.e., high-ranking individuals) within the engineering department. Specifically, in the
29 organization under study, high-ranking individuals engage in task-related interactions with other
30 supervisors' employees if doing so serves a task. As such, they are able to evaluate employee
31 effectiveness.²

53 been salient when they nominated employees for high effectiveness, see Appendix A.
54
55
56
57
58
59
60

1
2
3 In the investigation of performance consequences, the network data provide the
4 information for the independent and control variables. Ego's *number of dissonant ties* is the key
5 independent variable. To construct the variable, I counted the number of instances in which an
6 ego indicated seeking problem-solving assistance from a colleague with whom ego also found it
7 difficult to work. I control for the influence of ego's problem-solving and difficult ties on
8 performance as follows. In line with prior research on the influence of positive network ties on
9 performance (e.g., Brands & Kilduff, 2014; Tortoriello, 2015), I account for the *number of ties*
10 *seeking problem-solving assistance* and the tendency to bridge structural holes. Following
11 established practice (e.g., Tortoriello, 2015), the *structural holes* variable is calculated using
12 Burt's (1992) constraint measure subtracted from 1. With regard to the negative network, I
13 account for ego's *number of ties nominating others as difficult to work with* as a key component
14 of dissonant ties. I additionally control for their *number of nominations as difficult to work with*
15 provided by the alters (i.e., their in-degree in the difficult-tie network), as prior research has
16 shown that receiving negative tie nominations can negatively affect performance (Marineau et
17 al., 2016; Sparrowe et al., 2001). Finally, I control for ego's *formal hierarchical rank, tenure,*
18 *level of education, and gender.*

35
36
37
38
39
40 I rely on logistic regressions to investigate the consequences of seeking problem-solving
41 assistance from difficult colleagues for effectiveness nominations by direct supervisors. As my
42 second performance indicator is a count variable and as diagnostics revealed that it is
43 overdispersed, I use negative binomial regressions (Cameron & Trivedi, 2013) to examine the
44 influence of dissonant ties on effectiveness nominations by all formal leaders. In both cases,
45 standard errors are clustered around units.

Quantitative Analysis: Drivers of Dissonant Ties

I use ERGM to investigate the conditions that determine the likelihood of observing dissonant ties among engineers. ERGM is increasingly utilized to investigate tie formation in intraorganizational networks (e.g., Lomi et al., 2014; Rank, Robins, & Pattison, 2010). The approach accounts for tie interdependence in network data (Lusher et al., 2013) and treats the occurrence of network ties as the dependent variable. It enables estimation of parameters associated with the variables of theoretical interest, while providing an accurate characterization of the overall network structure in which individual ties are embedded (Lomi et al., 2014). More precisely, ERGM allows me to estimate the likelihood of observing problem-solving and difficult ties—separately and overlapping as a dissonant tie—as a function of two sets of variables: network patterns related to individual attributes, such as those describing employees' embeddedness in the organizational architecture; and network-endogenous patterns that capture the tendency of intraorganizational network ties to self-organize into meaningful structure (e.g., Lomi et al., 2014; Rank et al., 2010). By considering the influence of these two sets of network patterns on the likelihood of observing problem-solving, difficult, and dissonant ties all in one model, I can control for drivers of problem-solving and difficult network ties, thereby permitting empirical isolation of the drivers of dissonant ties.

In the following, I first describe the specific network patterns that I account for in the two variable sets, and then provide additional details on the estimation technique.

Individual attribute patterns. I use *formal hierarchical rank*, *tenure*, and *unit membership* to capture employees' embeddedness in the organizational architecture. I include other attributes that might influence the likelihood of observing dissonant ties as control variables. Relating to the ego, alter, and dyad perspectives on network tie formation, I transformed all attributes into variables for the empirical model as follows. First, I include

1
2
3 *attribute ego* and *attribute alter* patterns for formal hierarchical rank and tenure to capture the
4 influence of the two variables on individuals' tendencies to seek problem-solving assistance,

attribute ego and *attribute alter* patterns for formal hierarchical rank and tenure to capture the influence of the two variables on individuals' tendencies to seek problem-solving assistance, nominate others as difficult to work with, and employ dissonant ties (*attribute ego*), and their tendencies to be nominated as providers of problem-solving assistance, difficult to work with, and being approached with dissonant ties (*attribute alter*), respectively. Moreover, the model includes *attribute similarity/dissimilarity* patterns relating to formal hierarchical rank, tenure, and unit membership and additionally to employees' *level of education* and *gender*, which have been shown to affect the formation of positive and negative network ties (e.g., Ibarra, 1993; Lomi et al., 2014; Merluzzi, 2017). *Attribute similarity/dissimilarity* patterns refer to the dyad perspective on tie formation and account for the tendency of network ties to occur between individuals who are similar or dissimilar with respect to an attribute. For binary and categorical attributes (i.e., *formal hierarchical rank*, *gender*, and *unit membership*), they capture mere similarity, with a positive value indicating that the tied individuals have the same characteristic. For continuous attributes (i.e., *tenure* and *level of education*), they capture dissimilarity, more precisely, the difference between the values of the attribute. A negative value indicates a small absolute difference and suggests that individuals are similar. Finally, following Casciaro and Lobo (2015) and Lomi et al. (2014), I include data on *supervisor-supervisee relationships* to control for formal reporting lines. The influence of this dyadic attribute is captured in the form of *entrainment* patterns, which describe the likelihood of observing either type of tie if the dyadic attribute is present. All individual attribute patterns are included for positive and negative network ties per se as well as for multiplex, dissonant ties. Table 2 provides an overview of the individual attribute patterns included in the model.

--- Insert Table 2 about here ---

1
2
3 ***Network-endogenous patterns.*** As demonstrated by Rank et al. (2010), the formation of
4
5 intraorganizational networks cannot be fully understood without accounting for tendencies of
6
7 network ties to self-organize. Employees' networking behaviors are influenced by their own
8
9 network ties and by their network partners' ties with others. For instance, employees may seek
10
11 assistance from colleagues to whom many others also turn (a mechanism known as the "rich get
12
13 richer" or the "Matthew effect;" see Merton, 1968). To control for basic principles of network
14
15 self-organization, the model includes different network-endogenous patterns related to problem-
16
17 solving and difficult-tie networks. I selected these patterns based on previous studies on positive
18
19 and negative ties in the workplace (e.g., Lomi et al., 2014; Robins et al., 2009). I include
20
21 *reciprocity* as an important structuring principle of social networks (Gouldner, 1960). Moreover,
22
23 I account for differences in the engineers' tendencies to nominate others as a provider of
24
25 problem-solving assistance or as difficult to work with (*activity spread*) and to be nominated
26
27 (*popularity spread*). This controls for the in-degree and out-degree distributions of the two
28
29 networks, and reflects the finding that ties in social networks are seldom distributed evenly but,
30
31 rather, driven by such mechanisms as the above-mentioned Matthew effect. I also include
32
33 patterns to capture clustering—specifically, tendencies towards *transitive closure* and *cyclic*
34
35 *closure*—and I account for *multiple connectivity*, which may indicate the presence of brokerage
36
37 in the two networks (Robins et al., 2009).
38
39
40
41
42
43
44

45 In their entirety, the above patterns control for self-organizing principles in the positive
46
47 and negative tie networks from which dissonant ties emerge. Ignoring these patterns can lead to
48
49 spurious results regarding the drivers of tie formation (Krackhardt, 1987, 1988). To account for
50
51 endogenous dependencies determining the overlap of positive and negative ties, I include a
52
53 pattern that captures individuals' general tendencies to seek problem-solving assistance from
54
55
56
57
58
59
60

1
2
3 difficult colleagues (*general multiplexity*). This allows me to confirm whether dissonant ties are
4
5 more than a random by-product of the co-existence of positive and negative networks in the
6
7 workplace. Table 3 summarizes the endogenous patterns included in the model.
8
9

10
11 --- Insert Table 3 about here ---

12 ***Exponential random graph modeling.*** I use ERGM to investigate which patterns of
13
14 network ties characterize the observed network and, on that basis draw conclusions regarding the
15
16 drivers that generated the network. Unlike statistical approaches, such as regression analysis,
17
18 ERGM accounts for single tie observations not being independent of one another. It assumes a
19
20 stochastic process in which the presence of a particular tie is influenced by the two sets of
21
22 variables, individual attribute patterns and network-endogenous patterns. Parameters are
23
24 estimated for each pattern, with a positive (negative) value indicating that a network pattern is
25
26 observed more (less) often³ than would be expected if ties emerged randomly, conditional on all
27
28 other patterns in the model. The estimated parameter values are log odd ratios that can be
29
30 transformed into odd ratios by taking the exponential.
31
32
33
34

35 Formally, ERG models can be stated as:

$$36 \Pr(X = x \mid Y = y) = \binom{1}{x} \exp \left(\sum_Q \theta_Q Z_Q(x, y) \right), \quad (1)$$

37
38 where (i) X denotes the network variable for a network with n nodes and x denotes the
39
40 corresponding realizations; (ii) Y is an array of individual attribute variables with realizations y ;
41
42 (iii) $Z_Q(x, y)$ is a network statistic counting the number of network patterns of type Q for a
43
44
45
46
47
48
49

50
51
52 ³ A different logic, which is explained in the subsection on individual attribute patterns, applies to *attribute*
53 *similarity/dissimilarity* patterns.
54
55
56
57
58
59
60

1
2
3 particular network realization x and given the vector of attributes y ; (iv) θ_Q is the parameter
4
5 estimate corresponding to the statistic $Z_Q(x, y)$; and (v) κ is a normalizing constant included to
6
7 ensure that equation (1) is a proper probability distribution. The summation is taken over all
8
9 network patterns (Q) included in a given model. The probability of observing any network x in
10
11 this distribution (including the one that is actually observed) is dependent on the statistics $Z_Q(x,$
12
13 $y)$ and the corresponding parameter estimates θ_Q for all patterns in the model.
14
15

16
17 Based on Pattison and Wasserman (1999), this general form of ERGM has been extended
18
19 to the multiplex case to allow for the simultaneous investigation of two networks. In the
20
21 multiplex case, the formation of a network tie is assumed to depend on individual attribute
22
23 patterns, network-endogenous patterns, and other types of network ties. In other words, in line
24
25 with my theoretical assumptions regarding the interplay of positive and negative
26
27 intraorganizational networks, multiplex ERGM treats different types of ties as conditionally
28
29 dependent—the presence of a problem-solving tie is modelled considering the presence or
30
31 absence of a difficult network tie and vice versa. Accordingly, $Z_Q(x)$ is a multigraph in which
32
33 two nodes can be connected by multiple types of ties, such that:
34
35
36
37

$$Z_k(x) = \sum_{Q \in Q_k} \prod_{(i,j,m) \in Q} x_{ijm}, \quad (2)$$

38
39 where Q_k is a collection of isomorphic patterns Q of tie variables (Wang, 2013). I used Markov-
40
41 Chain Monte-Carlo maximum-likelihood implemented in the XPNet-software (Wang, Robins, &
42
43 Pattison, 2006) to estimate the parameter values for each pattern. Given the tie interdependence
44
45 in network data, all parameter estimates are dependent on one another. That is, the interpretation
46
47 of one pattern is conditional on all other patterns that characterize the observed network. In line
48
49 with existing ERGM applications (e.g., Zappa & Robins, 2016), I fixed the network density to
50
51 aid model convergence. To lessen the influence of outliers, I further fixed ties for employees
52
53
54
55
56
57
58
59
60

1
2
3 with in-degrees or out-degrees in either network that exceeded three standard deviations (for a
4 similar approach, see Lusher, Robins, Pattison, & Lomi, 2012).
5
6

7 8 **Qualitative Interviews**

9 I conducted semi-structured interviews with 18 engineers. Interviewees were selected to
10 ensure diversity in formal hierarchical rank, tenure, and unit membership. The interviews, which
11 typically lasted 45 to 75 minutes, were audio-recorded and transcribed. The interview questions
12 concerned different types of task-related interactions and network ties that formed part of the
13 engineers' day-to-day work, including perceptions of and interactions with difficult colleagues.
14 The interviews also provided insights into the types of engineering work in which individuals
15 were involved. For example, they revealed that some engineers worked on pooled tasks while
16 others worked on independent tasks, and that the workflow was sequential rather than reciprocal
17 (Thompson, 1967).
18
19
20
21
22
23
24
25
26
27
28
29

30 I used NVivo to content-analyze the interview transcripts, coding for information on why
31 relationships were perceived as difficult, what interactions with difficult colleagues comprised in
32 terms of behavioral repertoires, the performance consequences of these interactions, and the role
33 of the organizational architecture in employees' decisions to seek assistance from difficult
34 colleagues. In the following, I rely on this information to interpret the quantitative findings and
35 enhance the understanding of the mechanisms underlying the uncovered relationships.

41
42
43

44 **RESULTS**

45 **Descriptive Statistics**

46 As summarized in Table 4, the problem-solving network has a density of 5.7 percent,
47 while the difficult-tie network is sparser, with a density of 1.4 percent. This ratio of positive and
48 negative network ties is in line with prior research showing that negative ties in organizations are
49 rare (Baldwin et al., 1997; Labianca et al., 1998). Similarly, the number of dissonant ties is 50
50
51
52
53
54
55
56
57
58
59
60

1
2
3 and, thus, relatively low. However, as Labianca and Brass (2006) assert, it may be precisely the
4
5 rarity of negative—or, in this case, dissonant—ties that is responsible for their impact. Table 5
6
7 provides descriptive statistics and correlations for the variables included in the models.
8
9

10 --- Insert Table 4 about here ---

11
12 --- Insert Table 5 about here ---

13 14 **Consequences of Dissonant Ties**

15
16 Table 6 presents the results of the regression analyses examining the influence of
17
18 dissonant ties on individual performance. Models 1 and 2 present logistic regression results for
19
20 the effect of dissonant ties on performance evaluations provided by one's immediate supervisor.
21
22 The full Model 2 shows a positive influence of dissonant ties on egos' performance. Models 3
23
24 and 4 relate to performance evaluations by all formal leaders. Model 4 confirms the positive
25
26 effect of dissonant ties on performance. Overall, these findings support Hypothesis 1. The
27
28 control variables further suggest that formal hierarchical rank, tenure, and the bridging of
29
30 structural holes in the problem-solving network positively influence performance, while the
31
32 number of nominations as difficult to work with negatively affects performance evaluations.
33
34
35

36
37 --- Insert Table 6 about here ---

38
39 In line with Gibson's (2017) account of the strengths of mixed-method research, my
40
41 interviews enable triangulation of the findings by corroborating the positive performance impact
42
43 of dissonant ties. Moreover, they allow for deeper elaboration of the results by illustrating
44
45 cognitions and behavioral repertoires associated with dissonant ties. Finally, they enhance the
46
47 interpretation by substantiating the proposed theoretical mechanisms. First, and in line with the
48
49 second opening quote, the interviewees confirmed that dissonant ties provided access to unique
50
51 resources, as not everyone was willing to invest time and energy interacting with difficult
52
53 colleagues:
54
55
56
57
58
59
60

1
2
3 *If you are able to manage the relationship, you can gain beneficial information out of it.*
4 *It's hard work and for many people it might not seem worthwhile. But the people who do*
5 *step up become more effective because they can get all the information that they need.*
6
7

8 A high-ranking interviewee shared the following observation:
9

10 *You do see those sorts of challenges with certain people. Which then leads on to if that*
11 *sort of behavior is acceptable. ... A lot of these people have good technical knowledge and*
12 *they've got a lot to offer. But if people see it as challenging to approach them, then they*
13 *won't do that.*
14
15

16 In further support of the unique resources-mechanism, several interviewees mentioned
17 that individuals developed a “*reputation*” as difficult co-workers, which leads to them not being
18 approached by their colleagues. This was also supported by another interviewee who noted that
19 individuals avoided colleagues whom they perceived as “*frosty*” or “*grumpy*.” Moreover, the
20 interviewee’s statement reiterates the sentiment in the first opening quote, and supports the
21 second theoretical mechanism I propose as underlying the positive link between dissonant ties
22 and performance—seeking assistance from difficult colleagues serves to challenge assumptions:
23
24
25
26
27
28
29
30
31

32 *There is one person who's got nearly 30 years of experience. If you go to him with a*
33 *proposal, he'll say, "Nope, I'm not signing it." And where he's coming from is not that he*
34 *doesn't want to help you, he's challenging you to think of a better way of doing it. So he*
35 *is constructive in that way and I believe our ultimate solutions have been better for it. It's*
36 *just that people don't understand where he's coming from and avoid approaching him*
37 *because they feel that he's frosty or grumpy.*
38
39

40 Another interviewee’s reflections on the benefits of assistance from difficult colleagues
41 stressed the connection between dissonant ties and consideration of diverse perspectives:
42
43
44

45 *If I was to ask someone I found difficult for assistance, I think I would be perceived as*
46 *more open to multiple points of view and therefore not just stuck in making decisions*
47 *unilaterally. People would see me more as a team player, as someone who is able to*
48 *consider multiple points of view and synthesize an outcome that satisfies everyone. ... and*
49 *that's why I do it. I believe I'm more effective if I don't just take a singular point of view*
50 *and get multiple singular points of view on any one problem. I think that is a more*
51 *effective way of solving a problem, and a quicker one as well.*
52
53
54
55
56
57
58
59
60

1
2
3 The interviewees further discussed the cognitive processes triggered by dissonant ties.
4

5 For instance, one employee explained:
6

7
8 *If I strongly disagree with their point of view or if they haven't adequately dealt with my*
9 *concerns, I will consider additional options and look at other sources of information.*

10 Other interviewees described carefully preparing for this form of instrumental
11
12 networking, indicating increased cognitive activity even before actual problem-solving
13
14 interactions with difficult colleagues:
15

16
17 *I just really think about how I'm going to ask the question and the reasons for asking and*
18 *then I find that works far better, and I get a lot of benefit out of him. ... But you have to*
19 *really think about how you're going to raise a topic and talk about it. A vast number of*
20 *people find him extremely difficult when they go to him, and initially I did too, but I've*
21 *learned how to work that.*
22

23
24 A longer tenured interviewee—who, when asked about difficult colleagues instantly
25
26 asserted “*I'm classing myself as one of them,*”—confirmed:
27

28
29 *By now, people know to come to your desk and are prepared for the battle. They have to*
30 *build up a bit of courage and be prepared to be cross-examined.*
31

32 Finally, the interviewees clearly articulated that although they viewed interactions with
33
34 difficult colleagues as beneficial for achieving task-related goals, dissonant ties were still
35
36 perceived as unpleasant. Difficult colleagues were described as “*obnoxious,*” “*belligerent,*” or
37
38 “*a bit awkward,*” and they left the interviewees “*frustrated,*” “*exhausted,*” needing to “*go back*
39 *to [their] desk and have a rest.*” Taken together, my quantitative and qualitative findings provide
40
41 evidence that establishes dissonant ties as a construct with important implications for knowledge-
42
43 intensive work.

Drivers of Dissonant Ties

ERGM results. Table 7 presents the results of the quantitative analysis for the drivers of dissonant ties.⁴ The *general multiplexity* pattern is included as a control variable that captures the overall likelihood of observing dissonant ties. The positive parameter value (1.478, $p < 0.05$) indicates that engineers are more likely than would be expected in a random network to seek problem-solving assistance from colleagues they find difficult. In other words, dissonant ties are more than just a coincidence resulting from the co-existence of positive and negative networks in the workplace. Instead, engineers consciously employ these ties as a form of instrumental networking in anticipation of task and professional benefits.

With regard to the organizational architecture, the results show that from the ego perspective tenure matters for dissonant tie formation while formal hierarchical rank does not. In support of Hypothesis 2b, the *tenure ego multiplexity* parameter is negative (-0.167, $p < 0.01$). In contrast, the *formal hierarchical rank ego multiplexity* parameter is insignificant and I reject Hypothesis 2a. Engineers with shorter tenure but not low hierarchical rank are more likely to employ dissonant ties. In corroboration of the tenure finding and engineers' general tendency to rely on dissonant ties as instrumental networking behavior, an engineer who had been with the organization for less than two years emphasized that (s)he would not avoid difficult colleagues:

That's not my personal motto. For me, if I'm ever in that situation, I remind myself that I have to keep it professional.

Another engineer stressed his/her focus on the benefits of employing dissonant ties:

⁴ Appendix B contains supplemental analyses of conditional odds ratios calculated based on the parameter estimates in Table 7 to allow for extended interpretation of the findings.

1
2
3 *To solve the problem. Because my job depends on solving that problem. If I don't solve*
4 *that problem, it won't take long before I lose my job. No question about it. ... You have to*
5 *get over yourself.*
6

7
8 The quantitative results also support Hypotheses 3a and 3b, which address alters'
9
10 embeddedness in the organizational architecture. The negative *formal hierarchical rank alter*
11 *multiplexity* parameter indicates that high-ranking individuals are less likely to receive problem-
12 solving requests if they are simultaneously viewed as difficult. At the same time, the relationship
13
14 between alter tenure and the likelihood of observing dissonant ties (*tenure alter multiplexity*) is
15 positive. Thus, longer tenured difficult engineers are popular assistance providers. The
16
17 interviewees explained the difference between high-ranking and longer tenured assistance
18
19 providers as follows:
20
21
22
23
24
25

26 *If you're junior and you have a difficult interaction with a person who is high up in the*
27 *hierarchy, you're going to think that they think less of you after that interaction, and that*
28 *might then affect your career.*
29

30
31 Conversely:

32
33 *If you really want to step it up then you have to get along with the people who are more*
34 *experienced than you.*
35

36
37 The first opening quote illustrates what "getting along" might imply from the perspective
38
39 of a longer tenured engineer "*reputed to be difficult.*" A high-ranking employee further
40
41 explained that even management had noted difficulty of working with some longer tenured
42
43 engineers:
44

45
46 *We have a few senior [longer tenured] engineers, which, for various reasons, they're*
47 *very knowledgeable, but they're very difficult to get on with... certainly I know this*
48 *happens, and it's an area that we've identified pretty clearly and are working on trying to*
49 *break it down... we certainly have some weaknesses here, for sure. ... I wouldn't give up*
50 *because a person is difficult, but it's not an ideal situation.*
51

52
53 Finally, from the dyad perspective, similarity with respect to tenure but not with respect
54
55 to formal hierarchical rank mitigates the unpleasantness created by difficult ties. As the *formal*
56
57
58
59
60

1
2
3 *hierarchical rank similarity multiplexity* parameter is insignificant, I reject Hypothesis 4a. On the
4
5 other hand, in support of Hypothesis 4b, the *tenure dissimilarity multiplexity* parameter is
6
7 negative, indicating that dissonant ties are more likely among engineers who entered the
8
9 organization around the same time. While this finding provides evidence that dissonant ties are
10
11 formed within vertical boundaries, I also find that they tend to span horizontal boundaries. In
12
13 support of Hypothesis 4c, there is a negative relationship between working in the same unit and
14
15 the likelihood of observing dissonant ties between individuals (negative *unit membership*
16
17 *similarity multiplexity* parameter). An interviewee explained this as follows:
18
19

20
21
22 *Communicating across groups can be difficult because everyone's got different agendas,*
23 *everyone's got different goals, experience, ways that they normally communicate day-to-*
24 *day... I vary my communication styles depending on which group I am talking to.*
25

26
27 Another statement underscores the reasoning that engineers associate within-unit
28
29 dissonant ties with the cost of disturbing the unit's working climate and therefore avoid them:
30

31 *...people who do step up become more effective because they can get all the information*
32 *that they need. And if they can do it in a way that doesn't cause office riots—I can think*
33 *of a few *laughs*... We have quite robust conversations where people have opinions and*
34 *want to make sure that those opinions are heard, but this is not good in the sense that the*
35 *office sees it and it contributes to this [difficulty] perception.... It does get noticed, yeah.*
36 *We've found a few times we've said, 'can you go into a conference room please'*
37 **laughs*.*
38

39 --- Insert Table 7 about here ---
40

41
42 In addition to these findings, the control variables for patterns relating to dissonant ties
43
44 show that individuals are more likely to seek problem-solving assistance from difficult
45
46 colleagues with a similar level of education (negative *level of education dissimilarity multiplexity*
47
48 parameter). Moreover, individuals typically approach their direct supervisors for problem-
49
50 solving assistance, even if they find them difficult to work with (positive *supervisor dyadic*
51
52 *covariate multiplexity* parameter).
53
54
55
56
57
58
59
60

1
2
3 The results also show that different individual attribute and endogenous patterns
4 characterize the problem-solving and difficult-tie networks from which dissonant ties emerge.
5
6 With regard to individual attributes, the findings confirm that formal hierarchical rank is not
7
8 related to egos seeking problem-solving assistance per se (Cross & Cummings, 2004) while
9
10 tenure is positively related to it. In contrast, neither formal hierarchical rank nor tenure influence
11
12 ego's propensity to nominate others as difficult. In line with my assumptions, I also find positive
13
14 *formal hierarchical rank alter* and *tenure alter* parameters in both networks. High-ranking and
15
16 longer tenured individuals are more likely to receive problem-solving requests and to be
17
18 nominated as colleagues with whom it is difficult to work. The problem-solving network is also
19
20 characterized by homophilous tendencies with regard to formal hierarchical rank, tenure, and
21
22 gender, while the difficult-tie network is not. However, both networks are characterized by
23
24 positive *unit membership similarity* patterns: individuals are more likely to form problem-solving
25
26 ties and difficult ties within their units. Finally, the individual attribute patterns show that
27
28 engineers seek problem-solving assistance from their direct supervisors and that individuals with
29
30 dissimilar levels of education find each other difficult.
31
32

33
34
35
36
37 The endogenous patterns relating to problem-solving and difficult ties indicate that while
38
39 both networks are characterized by *reciprocity* and *transitive closure*, only the difficult-tie
40
41 network is characterized by positive and significant *activity spread* and *popularity spread*. These
42
43 patterns are indicative of network centralization—a few central individuals nominate and are
44
45 nominated by many colleagues as difficult co-workers. These results confirm that employees
46
47 often hold similar views on which individuals are difficult to work with (Robins et al., 2009).
48
49 The problem-solving network, on the other hand, is neither particularly centralized nor
50
51 decentralized. It is characterized by joint tendencies towards *transitive closure* and against *cyclic*
52
53
54
55
56
57
58
59
60

1
2
3 *closure*, which suggests hierarchical differences among individuals in the sense that only one
4 person in a triad is approached for assistance by the other two (Rank et al., 2010). Moreover, I
5 find tendencies against *multiple connectivity* in the problem-solving network, indicating that
6 short open paths and, thus, brokerage between individuals are avoided.
7
8
9
10

11
12 ***Goodness of fit diagnostics.*** In line with Hunter, Goodreau, and Handcock (2008), I
13 tested the ERG model's goodness of fit (GOF) by simulating 500 million networks from the
14 fitted model and comparing the characteristics of a random sample of 5,000 simulated networks
15 to the observed network's characteristics. Specifically, I first compared observed and simulated
16 network characteristics for all patterns included in the model and found that the GOF statistics
17 for each pattern were below $|t| = .1$ as threshold recommended by Robins et al. (2009) for these
18 patterns, thus indicating an excellent fit. As additional GOF diagnostic, Figure 2 provides
19 visualizations which allow graphically evaluating how well selected patterns of the simulated
20 networks fit the observed network. In line with the research question, the visualizations relate to
21 the patterns linked with Hypotheses 2 to 4. Each boxplot represents the simulated distribution of
22 a given pattern based on the 5,000 sampled networks which is compared to the observed network
23 represented by the black line. In each case, the black line aligns very closely with the median of
24 the simulated distribution. The visualizations, hence underscore the excellent model fit of
25 network patterns relating to formal hierarchical rank, tenure, and unit membership as critical
26 elements of the organizational architecture, thereby corroborating that the observed network
27 could well have resulted from the modeled drivers.
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 In line with common practice (e.g., Kim, Howard, Cox Pahnke, & Boeker, 2016; Robins
50 et al., 2009), I also compared network characteristics not in the model for the sample of
51 simulated networks to their observed values. As noted by Srivastava and Banaji (2011), this
52
53
54
55
56
57
58
59
60

1
2
3 approach represents a stringent test of model fit as it considers the model to fit well if it is able to
4 reproduce local patterns and global network characteristics of the observed network that were not
5 used to construct the model. I found that the majority of GOF statistics for network
6 characteristics not explicitly modeled were below the recommended threshold of $|t| = 2$ for non-
7 modelled patterns. Yet, a few slightly exceeded it⁵, which is not uncommon in ERGM
8 applications (e.g., Robins & Lusher, 2013; Srivastava & Banaji, 2011). Overall, the variables of
9 interest and most other features of the data can be adequately reproduced based on the model,
10 indicating that the observed network could have resulted from the modeled drivers.

23 **DISCUSSION**

24
25 In this study, I introduced dissonant ties as a new construct that captures the overlap of
26 network ties characterized by an individual's conflicting cognitions of another person. I utilized a
27 mixed-method approach to develop a comprehensive theory of dissonant ties that simultaneously
28 addresses the consequences and drivers of employees' purposeful employment of cognition-
29 based positive-negative ties as instrumental networking behavior. Drawing a link to performance
30 consequences, I establish dissonant ties as a construct with significant implications for
31 management and organization theory. At the same time, this link demonstrates that employees'
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46

47 ⁵ For instance, GOF statistics for complex patterns associated with mixed triadic closure do not fit ideally, which I
48 address in my discussion of this study's limitations and opportunities for future research. Moreover, GOF statistics
49 for global network characteristics associated with the standard deviation of the in-degree distribution and global
50 transitive clustering of the problem-solving network were suboptimal, for instance as some engineers received a
51 very high number of nominations as assistance providers. To explore the latter, Appendix C contains an extended
52 GOF analysis including visualizations that allow for the graphical evaluation of model GOF with regards to the
53 global characteristics of the observed problem-solving and difficult-tie networks.
54
55
56
57
58
59
60

1
2
3 assignment of value to this counter-attitudinal behavior is justified. Subsequently, the study
4 emphasizes elements of the organizational architecture as critical determinants of positive-
5 negative tie multiplexity in the workplace. It demonstrates that the benefits and costs that
6 employees associate with dissonant tie formation and, hence, their willingness to engage in this
7 potentially unpleasant but beneficial form of networking are context driven.
8
9

10
11 Overall, the study shows that the consequences and drivers of dissonant ties differ from
12 the consequences and drivers of their component parts, that is, positive and negative ties in
13 intraorganizational networks. The interplay of these two types of networks and their convergence
14 into multiplexity give rise to a unique third type of network tie that deserves attention—dissonant
15 ties.
16
17

18 **Contributions**

19
20 By introducing dissonant ties to the literature, my study makes three main contributions
21 to organizational network theory. First, I jointly investigate the construct's consequences and
22 drivers, which allows me to highlight previously overlooked ways in which individuals secure
23 beneficial resources. In doing so, I draw attention to agency in tie formation (e.g., Ahuja et al.,
24 2012; Emirbayer & Mische, 1998) and extend the logic of cognitive-consequentialist networking
25 behavior (Borgatti & Cross, 2003; Nebus, 2006) to the new type of cognition-based positive-
26 negative network tie. This approach to dissonant ties demonstrates that networking may involve
27 engagement in counter-attitudinal behavior as long as the distinct benefits associated with tie
28 formation exceed the perceived costs. By linking these benefits and costs to employees'
29 embeddedness in the organizational architecture, I explicitly take Casciaro et al.'s (2014: 727)
30 suggestion that "[u]nderstanding agency in networking behavior requires an understanding of the
31 structural context within which agency emerges" into account.

51
52
53
54
55
56
57
58
59
60

1
2
3 Second, my research challenges and refines key assumptions of social ledger theory
4
5 (Labianca & Brass, 2006). This theory, which calls for the joint analysis of positive and negative
6
7 networks that co-exist in the workplace, associates positive ties with benefits and negative ties
8
9 with liabilities, and depicts them as mutually exclusive sides of the social ledger. It assumes that
10
11 individuals' positive and negative ties are not directed at the same individuals, and that their
12
13 respective benefits and liabilities counterbalance each other. In merging the joint focus on
14
15 positive and negative ties with a network multiplexity perspective, this study offers an extended
16
17 view of the interplay between positive and negative networks in the workplace. Moving beyond
18
19 the accounting logic inherent in social ledger theory, it demonstrates that the consequences of
20
21 positive and negative ties do not necessarily counterbalance each other and that negative ties do
22
23 not always produce liabilities. Overlapping with positive network ties, they yield distinct
24
25 instrumental benefits. Similarly, with regards to the drivers of tie formation, the extended view
26
27 presented here suggests that employees weigh the combined benefits of the positive and negative
28
29 tie components against their combined costs. As such, this view puts key propositions of social
30
31 ledger theory into perspective. It offers a synergistic understanding of the interplay of positive
32
33 and negative networks and their convergence into dissonant ties, thereby also adding to research
34
35 on network multiplexity, which has been largely restricted to investigating overlap of positive—
36
37 professional or personal—network ties (e.g., Rank et al., 2010; Soda & Zaheer, 2012).
38
39
40
41
42
43

44 Finally, the study's focus on the drivers of dissonant ties advances the literature on
45
46 intraorganizational networks. The results on tie formation confirm that problem-solving and
47
48 difficult ties overlap more often than would be expected by chance. Hence, similar to ambivalent
49
50 relationships in the workplace (Melwani & Rothman, 2015; Methot et al., 2017), dissonant ties
51
52 can be seen as an inherent part of intraorganizational networks in knowledge-intensive
53
54
55
56
57
58
59
60

1
2
3 organizations. In highlighting employees' embeddedness in the organizational architecture as a
4 boundary condition for tie formation, I offer an explanation for the conflicting findings of
5
6 previous research. In particular, Casciaro and Lobo (2008) show that individuals avoid disliked
7
8 others for assistance. However, these authors focus on affect-based, rather than cognition-based,
9
10 negative ties, and do not provide information on the extent or the conditions under which they
11
12 might observe an overlap between dislike and assistance seeking. In this respect, the findings
13
14 presented here provide a more nuanced understanding of employee networking.
15
16
17
18

19 I demonstrate that formal hierarchical rank, tenure, and unit membership critically affect
20
21 the employment patterns of dissonant ties. Due to their different power and resource implications
22
23 and ways of structuring the knowledge-intensive workplace, these three elements of the
24
25 organizational architecture exert unique influences on evaluations of the benefits and costs
26
27 associated with dissonant ties. From the ego perspective, tenure, while not linked to difficult
28
29 working relationships, is positively related to seeking problem-solving assistance but negatively
30
31 influences dissonant tie formation. The longer tenured an engineer, the more that engineer will
32
33 seek problem-solving assistance in general, presumably because he or she works on more
34
35 complex tasks (Zacher & Frese, 2011). Yet the shorter tenured an engineer, the more that
36
37 engineer employs dissonant ties to reap the distinct tie-inherent benefits. In contrast, ego's
38
39 formal hierarchical rank is unrelated to positive, negative, or dissonant tie formation. With
40
41 regards to the latter, a leveling effect may be in play: while low-ranking individuals should
42
43 associate high benefits with assistance from difficult colleagues, they still face costs; conversely,
44
45 high-ranking individuals might associate fewer costs with dissonant ties, as their formal
46
47 hierarchical rank provides them with the authority to admonish difficult colleagues.
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 From the alter perspective, both longer tenured alters and high-ranking alters are popular
4 providers of problem-solving assistance and they tend to be perceived as difficult. However, only
5 alter tenure is positively related to dissonant tie formation. In comparison, there is a strong
6 tendency to avoid dissonant ties with high-ranking alters, presumably because they possess
7 formal power and control over the allocation of means, rewards, and punishments, making
8 interactions with them disproportionately risky.
9

10
11 The dyad perspective indicates that similarity with respect to tenure but not formal
12 hierarchical rank affects dissonant tie formation. While homophilous tendencies for both tenure
13 and formal hierarchical rank promote problem-solving interactions per se, only tenure-related
14 homophily seems to attenuate the unpleasantness associated with tie-inherent cognitive
15 inconsistencies, thereby fostering individuals' willingness to employ dissonant ties. Notably,
16 similarities in formal hierarchical rank and tenure are unrelated to difficult tie formation.
17

18
19 Overall, the findings establish tenure as a more critical driver of dissonant tie formation
20 than formal hierarchical rank. In line with my findings, prior research (e.g., Gambardella, Panico,
21 & Valentini, 2015; Ibarra, 1993), reinforced by my interviews, indicates that this difference in
22 relevance might be attributable to the knowledge- and engineering-intensity of the workplace.
23 For knowledge-workers, tenure appears to be the more salient driver of networking behavior
24 because it is associated with subject-matter expertise, experience, and expert careers, which they
25 often prioritize over formal hierarchical rank, power credentials, and management
26 responsibilities (Allen & Katz, 1986; Brousseau et al., 1996). As a consequence, tenure
27 influences dissonant tie formation from the ego, alter, and dyad perspectives alike, while formal
28 hierarchical rank does not. From the alter perspective in specific, tenure is typically associated
29 with technical support and higher levels of expertise, which are more critical for day-to-day work
30
31
32
33

56
57
58
59
60

1
2
3 in complex engineering than is administrative support provided by high-ranking employees.
4
5 Dissonant ties with longer tenured alters are, therefore, perceived as especially beneficial for
6
7 knowledge-intensive work.
8
9

10 Finally, the third element of the organizational architecture under investigation from the
11
12 dyad perspective, unit membership, is positively related to positive and negative tie formation
13
14 per se. Engineers are more likely to establish difficult ties and problem-solving ties with
15
16 colleagues from their own units. At the same time, the results confirm that dissonant ties are
17
18 more likely to span unit boundaries in knowledge-intensive organizations—these network ties
19
20 combine the distinct benefits of dissonant ties with access to heterogeneous inputs not available
21
22 in ego's own unit. Moreover, the unit boundary creates a safe distance between ego and difficult
23
24 alters.
25
26
27

28 The dyad perspective sheds light on a seemingly counterintuitive difference among the
29
30 three architectural elements that is, nevertheless, consistent with the cognitive-consequentialist
31
32 approach to instrumental networking. I show that dissonant ties are formed within vertical
33
34 boundaries but across horizontal boundaries of the organization. Thereby, this study adds to
35
36 research on the drivers of boundary spanning as a topic of foremost interest for organizational
37
38 network scholars (e.g., Lomi et al., 2014; Soda et al., 2018). In this connection, the empirical
39
40 finding that the formation of difficult ties is unrelated to similarities in formal hierarchical rank
41
42 and tenure, but more likely to occur within, rather than across unit boundaries, deserves
43
44 attention. Focusing on the negative component of dissonant ties, it refutes the assumption that
45
46 homophily as a mechanism driving positive network ties can simply be reversed and applied to
47
48 negative networks. As postulated by Labianca and Brass (2006: 599-600), “the formation of
49
50 negative relationships is not the mere opposite of the way positive relationships form.”
51
52
53
54
55
56
57
58
59
60

1
2
3 Accordingly, cultural differences or ingroup-outgroup categorizations (Turner, 1987) triggered
4 by unit membership are not the main drivers of difficult ties. Instead, the observed boundary-
5 spanning tendencies are distinctly related to employees relying on dissonant ties as an
6 instrumental networking behavior.
7
8
9
10

11 **Limitations and Future Research**

12
13
14 This study's limitations provide some guidance on future research opportunities regarding
15 dissonant ties. First, the cross-sectional nature of the empirical data does not allow for causality
16 testing of the link between dissonant ties and performance or the interplay between positive and
17 negative network ties. While theoretical arguments and qualitative interviews offer support for
18 the proposed causalities, performance may also influence dissonant tie formation. For instance,
19 high performers might be more confident in approaching difficult colleagues. However, based on
20 existing theory as well as meta-analytic evidence on the network-performance relationship
21 (Balkundi & Harrison, 2006), the inverse seems to be the stronger and more direct causal
22 relationship. Ultimately, experimental studies and in-depth longitudinal research are needed for
23 confirmation. Such research should also address the co-evolution of positive and negative tie
24 networks and, thereby, revisit the assumption that multiplex network ties are particularly robust
25 (e.g., Soda & Zaheer, 2012). This assumption might not apply to the extended conceptualization
26 of network multiplexity that incorporates simultaneity of positive and negative ties. Instead,
27 perceptions of difficulty may diminish after repeated problem-solving interactions. Similarly,
28 problem-solving relationships may become difficult if assistance providers perceive the costs of
29 helping as excessive or as threatening their own task performance (Bergeron, 2007). Against this
30 background, future research adopting a dynamic perspective to investigate the short-term
31 fluctuations and long-term stability of dissonant ties would be of interest.

55
56
57
58
59
60

1
2
3 Second, this study's investigation of performance consequences serves to establish
4
5 dissonant ties as a construct with significant theoretical and practical implications but it lacks
6
7 depth. The unidimensionality of the performance measure, which only accounts for
8
9 effectiveness, constitutes one limitation. It would be interesting to examine whether dissonant
10
11 ties have equally positive consequences for individuals' efficiency or innovativeness. In addition,
12
13 while I demonstrate the functional value of dissonant ties for performance, they might still also
14
15 have negative consequences. Several statements made during the interviews as well as prior
16
17 inconsistency research indicate that dissonant ties may trigger negative affective responses
18
19 (Hinojosa et al., 2017) and impair individuals' work satisfaction or well-being. Similarly, I
20
21 propose alternative mechanisms that are likely to give rise to the link between dissonant ties and
22
23 performance, but I am unable to test them through quantitative analyses. Research is needed to
24
25 provide insights into the relative importance of each mechanism by testing for mediators of the
26
27 dissonant tie-performance relationship.
28
29
30
31
32

33 Third, my conceptualization of dissonant ties focuses on the mere simultaneity of
34
35 cognition-based positive and negative network ties. Following a tradition in organizational
36
37 network research, the next step would be to refine this conceptualization. For instance, future
38
39 studies should account for the strength of the positive and negative tie components to offer a
40
41 more nuanced understanding of the relationship between dissonant ties and performance.
42
43 Similarly, the difficult tie component could be further differentiated based on the distinct work-
44
45 related qualities to which it refers (i.e., being perceived as arrogant, having different priorities, or
46
47 hindering work etc.). Finally, advancing the investigation of drivers of dissonant ties by
48
49 considering triads in addition to accounting for ego, alter, and dyad might reveal further insights.
50
51
52
53
54 As the goodness-of-fit simulations indicate, mixed triads comprising positive and negative ties
55
56
57
58
59
60

1
2
3 between three individuals might play a role in the formation of dissonant ties. A useful first step
4
5 in approaching this issue may be to extend the notions of balance theory (Heider, 1958) to
6
7 positive-negative multiplexity, as seen in Sytch and Tatarynowicz's (2014) investigation of inter-
8
9 organizational networks.

FIGURE 1 Conceptual Framework

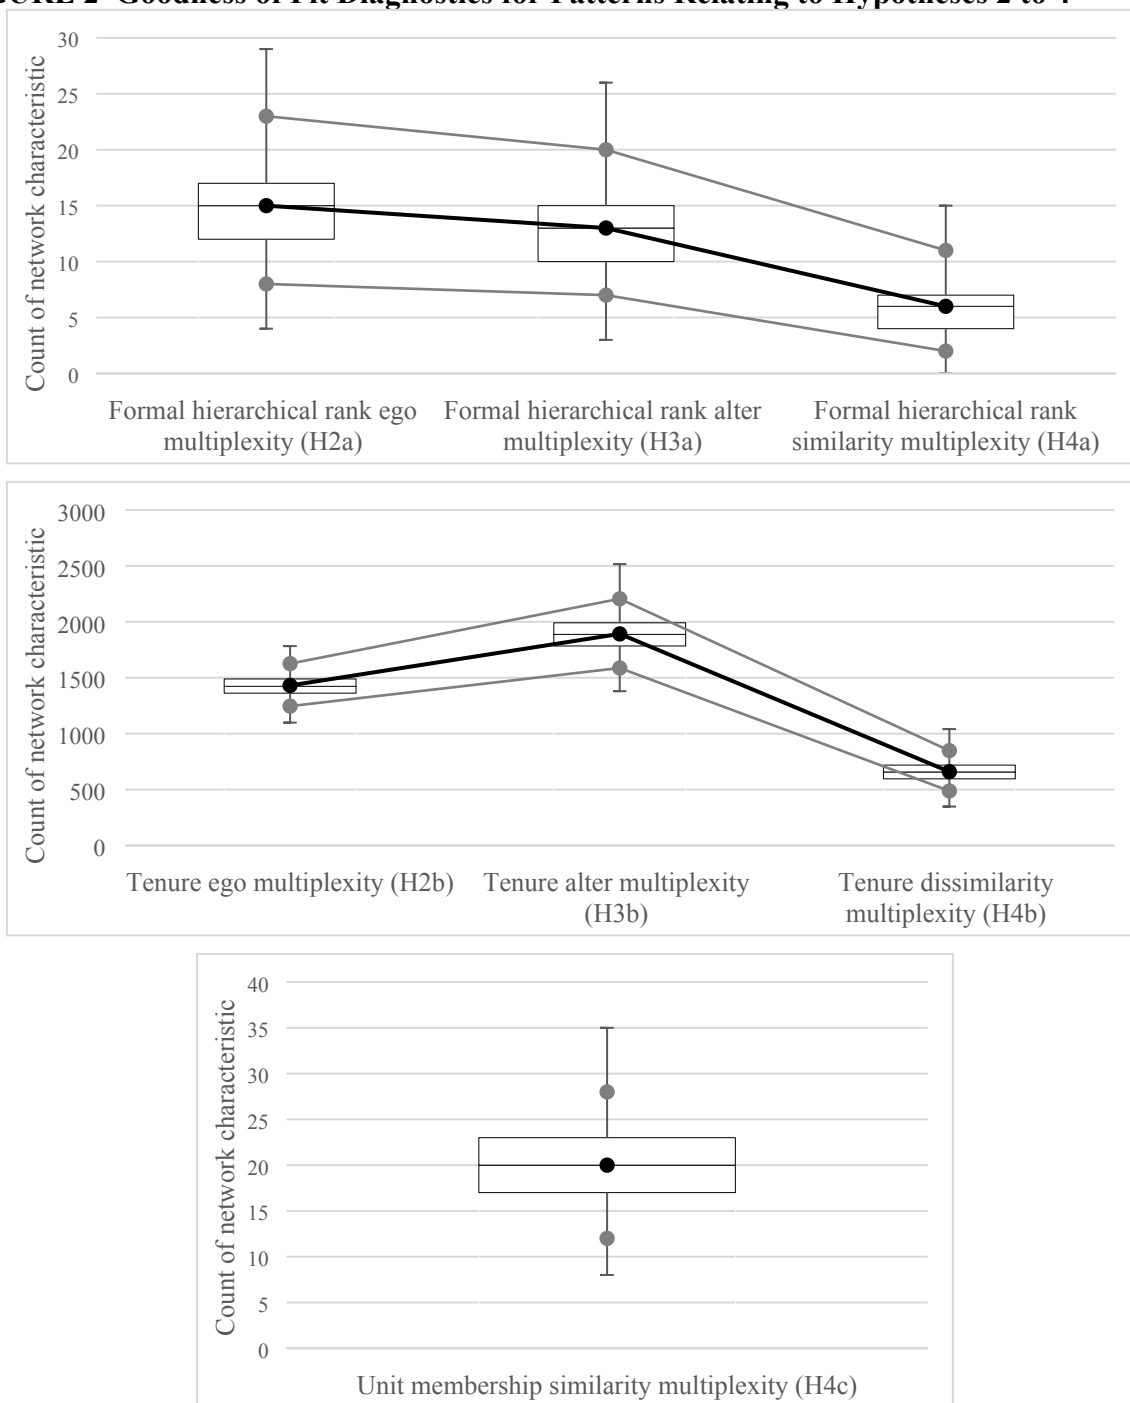

FIGURE 2 Goodness of Fit Diagnostics for Patterns Relating to Hypotheses 2 to 4

Note: The black solid line represents a given statistic from the observed networks. The boxplots represent the same statistic from the 5000 sampled simulated networks; they include the median and interquartile range. The light-gray lines represent the range in which 95 percent of simulated networks fall.

TABLE 1 Schematic Depiction of Ego, Alter, and Dyad Perspectives

Ego perspective		Influence of ego's formal hierarchical rank (H2a) and tenure (H2b) on dissonant tie formation
Alter perspective		Influence of alter's formal hierarchical rank (H3a) and tenure (H3b) on dissonant tie formation
Dyad perspective		Influence of similarity in formal hierarchical rank (H4a), tenure (H4b), and unit membership (H4c) on dissonant tie formation

TABLE 2 Individual Attribute Patterns Included in Empirical Model of Drivers of Dissonant Ties

Variable	Visualization	Included to account for	Network statistics
Attribute ego multiplexity		Tendency for individuals with a specific continuous or binary attribute to seek problem-solving assistance from a person <i>and</i> nominate that person as difficult to work with	$\sum x_{ijm}y_i$
Attribute ego		Tendency for individuals with a specific continuous or binary attribute to seek problem-solving assistance or nominate others as difficult to work with	$\sum x_{ij}y_i$
Attribute alter multiplexity		Tendency for individuals with a specific continuous or binary attribute to be nominated by others as providers of problem-solving assistance <i>and</i> difficult to work with	$\sum x_{ijm}y_j$
Attribute alter		Tendency for individuals with a specific continuous or binary attribute to be nominated by others as providers of problem-solving assistance or difficult to work with	$\sum x_{ij}y_j$
Attribute similarity/dissimilarity* multiplexity		Tendency for problem-solving <i>and</i> difficult ties to occur between dyads of individuals who are (dis-)similar with respect to a categorical, continuous, or binary attribute	$\sum x_{ijm}y_i y_j$
Attribute similarity/dissimilarity*		Tendency for problem-solving or difficult ties to occur between dyads of individuals who are (dis-)similar with respect to a categorical, continuous, or binary attribute	$\sum x_{ij}y_i y_j$
Dyadic attribute entrainment multiplexity		Tendency for problem-solving <i>and</i> difficult ties to occur between dyads of individuals if a dyadic attribute is present	$\sum x_{ijm}v_{ij}$
Dyadic attribute entrainment		Tendency for problem-solving or difficult ties to occur between dyads of individuals if a dyadic attribute is present	$\sum x_{ij}v_{ij}$

Note. \longrightarrow = seeking problem-solving assistance *or* nominating others as difficult to work with; \bigcirc = individual; \bullet = individual with a binary or categorical attribute or high values on a continuous attribute; \curvearrowright = dyadic covariate. * For binary and categorical attributes, the variable captures similarity. For continuous attributes, it captures dissimilarity (i.e., the difference between values of the attribute). A negative value indicates a small difference, suggesting that individuals are similar. Statistical notation: x_{ij} = network tie between individuals i and j , x_{ijm} = multiplex network tie between individuals i and j , y_i = individual attribute of i or j , v_{ij} = dyadic covariate between i and j .

TABLE 3 Network-endogenous Patterns Included in Empirical Model of Drivers of Dissonant Ties

Variable	Visualization	Included to account for	Network statistics
Reciprocity		Tendency to reciprocate problem-solving or difficult relationships	$\sum x_{ij}x_{ji}$
Activity spread		Tendency for variation in the degree to which individuals seek problem-solving assistance or nominate others as difficult to work with	$\sum_{k=2}^{n-1} (-1)^k \frac{S_{k_out}}{\lambda^{k-2}}$
Popularity spread		Tendency for variation in the degree to which individuals are nominated as providers of problem-solving assistance or as difficult to work with	$\sum_{k=2}^{n-1} (-1)^k \frac{S_{k_in}}{\lambda^{k-2}}$
Transitive closure		Tendency for triadic closure in problem-solving or difficult-tie networks, indicative of transitivity	$\lambda \sum_{i < j} x_{ij} \left\{ 1 - \left(1 - \frac{1}{\lambda} \right)^{L_{T2ij}} \right\}$
Cyclic closure		Tendency for cyclic closure in problem-solving or difficult-tie networks, indicative of a prevailing generalized exchange	$\lambda \sum_{i < j} x_{ij} \left\{ 1 - \left(1 - \frac{1}{\lambda} \right)^{L_{C2ij}} \right\}$
Multiple connectivity		Tendency for problem-solving or difficult ties to form as part of formations involving multiple short paths between individuals	$\lambda \sum_{i < j} \left\{ 1 - \left(1 - \frac{1}{\lambda} \right)^{L_{T2ij}} \right\}$
General multiplexity		Tendency to seek problem-solving assistance from a colleague nominated as difficult to work with	$\sum x_{ijm}$

Note. \longrightarrow = seeking problem-solving assistance *or* nominating others as difficult to work with; \bigcirc = individual. Statistical notation: x_{ij} = network tie between individuals i and j , x_{ijm} = multiplex network tie between individuals i and j , n = number of individuals included in the network, S stands for “star” and the subscript k indicates the size of the star (e.g., 2-star, 3-star, ... 1 k-star), k_in refers to the in-degree of individuals, k_out refers to the out-degree of individuals, λ is a dampening factor (Snijders, Pattison, Robins, & Handcock, 2006), L_{*2ij} represents the number of indirect paths of length 2 between i and j with T standing for transitive patterns and C standing for cyclic patterns (Lomi et al., 2014).

TABLE 4 Descriptive Statistics for the Networks

Statistic	Problem-solving network	Difficult-tie network
Density	0.057	0.014
# of ties	1663	413
Reciprocity rate	0.275	0.102
Mean in-/out-degree	9.725	2.415
Standard deviation out-degree	10.483	3.261
Minimum out-degree	0	0
Maximum out-degree	47	22
Standard deviation in-degree	9.47	4.170
Minimum in-degree	0	0
Maximum in-degree	68	23

APPENDIX A Selected Quotes from Formal Leaders on Daily Working Procedures and Effectiveness

Several high-ranking interviewees confirmed that they engaged in task-related interactions with other supervisors' employees, allowing them to evaluate their effectiveness in the first place:

[Name], for example, tends to delegate most of the work to the engineers, so my interaction is actually not much with [name] but more with the guys. [...] They are less experienced, so I typically offer support to them as well. Is it part of my job? I guess. I don't see it otherwise because ultimately we're trying to reach the same solution.

and

I talk to their employees as well, yeah. In fact, most of the time it's a 50/50 thing [...] I'll go straight to the person [...] I deal with some things that are fairly urgent and I need a quick response.

and

I sit in on multiple design reviews and similar meetings a week to see all the structure side - that's my prime responsibility.

Describing the work within the engineering department, they emphasized high pressure to provide timely solutions that reduce costs and improve working processes. Their quotes underline the complexity and knowledge-intensity of the engineers' work. Exemplary statements are:

We provide design solutions and analysis solutions. We make design changes for cost reduction and also defect reductions in support of the production line, so if there is a problem down the line with a design that we can make better, then that is a change that we go through. ...making sure that we do the work correctly in terms of procedures, making sure that the people doing the work are supported in completing the task.

and

We'd be running fatigue tests... and we had to get a test ready in three or four weeks. It was just a shambles. But a lot of the young guys did really good. ... The people who actually helped me organize that test have moved on [to high-ranking positions in the company]. They've done really well. Solutions were worked out.

and

Because the cost of manufacturing the product is too high... the challenge... is to work out ways to redesign either the components themselves or the manufacturing process to reduce cost. And some of the ideas that we've come up with and that we've implemented this year have had a high disruption. [Gives two technical examples.] So these are examples of what disruptive requests are and their scale could be huge, but the driver is all around cost reduction.

The following quotes illustrate behavioral expectations and reflect that there is a fine line between exploration and exploitation:

It's very easy to get pulled into many side elements or side branches in a project and there are times when you just need to stop. Don't investigate all the side roads, just keep going down there and execute on what we need. So, the business is becoming very focused around fabrication rate and cost and engineering costs and reduction of hours and effective use of hours.

and

We're always encouraging people to come up with new ideas and new designs and better ways of doing things. ...we do focus a lot on continuous improvement as well, so looking at processes that we have in place, what works, what doesn't work. ...we have weekly design reviews. So we make sure that the teams bring their design to a forum, and other design leads or analyst leads provide feedback, and it's a good, open discussion in terms of the maturity of their design and how it is going.

One formal leader described the case of an employee who in his words "wasn't a great performer" and who struggled to integrate knowledge from different functional areas, trying to get him to:

...study his functions separately at a detail level. "Go and read the procedures relative to planning. Go and read the procedures relative to manufacturing engineering."

and commented that in such cases:

They [the engineers] just don't seem as agile in their thought process... they don't seem to be able to flip over the mind-set.

Finally, also commenting on performance assessment, another interviewee talking about engineers ("the technical guys") in comparison to administrative managers stated:

The technical guys are more about the technical specialty that they are recognized for... their performance isn't rated on how well the business is going or how well the engineering group is going. It's much more about quality of technical answers.

APPENDIX B Qualitative Implications of the ERGM Estimates

To deepen the interpretation of the ERGM results, I transformed the parameter estimates into conditional odds ratios (Lomi et al., 2014; Robins & Daraganova, 2013). This approach can be compared to calculating the odds ratio in a logistic regression with the difference that the ERGM-based odds refer to the likelihood of observing a network tie. They are conditional on all other things being equal—a tie is in the identical structural position (captured by the network endogenous patterns in the model) and the involved employees have the same values on all other attributes. Because no two ties may actually fulfil this condition, calculating the conditional odds can best be seen as “abstract thought experiment” that “does help us interpret attribute effects” (Robins & Daraganova, 2013: 97)

How to calculate conditional odds differs for unit membership as categorical attribute variable, formal hierarchical rank as binary variable, and tenure as continuous variable. Therefore, the following analyses are presented according to types of variables, from least to most complex, rather than ego, alter, and dyad perspectives used to structure the main body of the manuscript.

Unit membership. With regards to unit membership as categorical variable, the conditional odds are calculated by simple exponentiation of the estimated unit membership similarity parameters. For problem-solving and difficult tie estimates, they refer to the likelihood of observing each type of tie while holding everything else constant: *ceteris paribus*, the odds of observing problem-solving ties among members of the same unit are more than twice ($\exp(0.821) = 2.3$) the odds of observing problem-solving ties across units. The odds of observing difficult ties within units are four times ($\exp(1.364) = 3.9$) the odds of observing them across unit boundaries. In contrast, for multiplex parameter estimates, the conditional odds reflect the extra effect given by both types of ties being present at the same time. When an individual has a difficult working relationship with a colleague in the same unit, the odds for this individual to also seek problem-solving assistance from the colleague—thereby establishing a dissonant tie—are more than halved ($\exp(-0.858) = 0.42$) within as compared to across unit boundaries. This implies that the within-unit “advantage” for problem-solving ties is more than cancelled out when members of a dyad are simultaneously connected by a difficult working relationship; in line with the negative and significant ERGM parameter estimate, employees are more likely to establish dissonant ties across unit boundaries.

Formal hierarchical rank. For formal hierarchical rank as binary variable the calculation of conditional odds ratios becomes gradually more complex, because ego, alter, and similarity effects play a role. Given that high-rank = 1, the case of two employees without the attribute (i.e., low-ranking employees) can be defined as the baseline and conditional odds ratios for ego, alter, and similarity effects are calculated relative to that baseline. For ego and alter effects, the odds result from exponentiation of the estimated parameters. In contrast, when computing the odds for observing ties between two high-ranking employees (compared to two low-ranking employees as the baseline), ego and alter effects need to be taken into account. The latter odds are calculated as $\exp(\theta_{\text{ego}} + \theta_{\text{alter}} + \theta_{\text{similarity}})$. Results based on this logic for problem-solving, difficult, and dissonant ties are shown in Table B1.

For the interpretation, I concentrate on formal hierarchical rank alter effects because the parameter estimates they are based upon are consistently statistically significant in the ERGM model. All else being equal, the odds to be approached for problem-solving assistance are $\exp(0.139) = 1.15$ for high-ranking as compared to low-ranking alters. The odds of them being nominated as difficult are more than twice the odds of their low-ranking colleagues. In contrast,

the odds of a receiving problem-solving requests drop to about one-seventh for high-ranking as compared to low-ranking alters if a difficult relationship is simultaneously present.

TABLE B1 Conditional Odds for Observing Problem-Solving, Difficult, and Dissonant Ties Based on Formal Hierarchical Rank

	Problem-solving ties	Difficult ties	Dissonant ties
Baseline	1.00	1.00	1.00
Formal hierarchical rank ego	1.11	0.86	1.39
Formal hierarchical rank alter	1.15	2.12	0.14
Formal hierarchical rank similarity	2.05	1.17	0.62

Tenure. For tenure as continuous variable, I follow advice by Robins and Daraganova (2013) and calculate conditional odds by assigning attribute scores based on the variable's mean (= 10.23) and standard deviation (= 9.51) to hypothetical egos and alters.

For ego and alter effects, the calculation follows the above logic. From the ego perspective, the modelling results indicate that the odds of seeking problem-solving assistance increase by $\exp(0.007 * 9.51) = 1.07$ if ego tenure rises by one standard deviation. As the estimate for difficult tie formation is insignificant, I refrain from interpreting its effect size. Regarding dissonant ties, the odds of seeking problem-solving assistance decrease by 0.2 per rise in standard deviation if a difficult working relationship is simultaneously present, other conditions being equal. From the alter perspective, the odds of employees to be approached for problem-solving assistance increase by 1.13, to be nominated as difficult by 1.18, and by an additional factor of 4 for both types of ties being present at the same time if alter tenure rises by one standard deviation.

For the dyad perspective, that is, similarity in tenure, first remember that the estimated parameters capture dissimilarity, specifically the difference between the values of the attribute. Conditional odds for observing ties between employees from the dyad perspective are calculated by assigning tenure values to ego and alter. I assigned values of the mean plus/minus one standard deviation reflecting short and long tenure respectively. The conditional odds are computed as $\exp(\text{attribute value ego} * \theta_{\text{ego}} + \text{attribute value alter} * \theta_{\text{alter}} + (|\text{attribute value ego} - \text{attribute value alter}|) * \theta_{\text{dissimilarity}})$.

Following the example of Lomi et al. (2014), results are summarized in Table B2 for problem-solving, difficult, and dissonant ties. Each entry reflects the odds of a tie from ego with long/short tenure to alter with long/short tenure, compared to a tie from a baseline ego to a baseline alter. The baseline refers to egos and alters who have just entered the organization; the odds observing a tie between two employees with short tenure ($10.23 - 9.51 = 0.72$) come very close to this baseline.

Results for problem-solving ties show that, relative to the baseline, the odds for employees with long tenure decrease to 0.85 for seeking problem-solving assistance from employees with short tenure and rise to 1.48 for problem-solving assistance from employees with similarly long tenure. For difficult ties, the odds to find alters with long tenure difficult are 1.38 compared to the baseline for egos with short tenure and 1.48 for egos with similarly long tenure. As only the estimate for tenure alter is actually statistically significant in the ERG model, the observed differences with regards to difficult tie formation are driven by an alter effect rather than a dissimilarity effect. Finally, when an ego with short tenure has a difficult relationship with

1
2
3 a long tenured alter, the odds of simultaneously observing a problem-solving tie decline only
4 slightly to 0.81 relative to the baseline. In contrast, for long tenured alters the odds of observing a
5 problem-solving and difficult tie with an ego with short tenure at the same time are close to zero
6 and with an ego with similarly long tenure are 0.66 relative to the baseline. In line with the
7 significant ERGM parameter estimates, dissonant ties, hence, tend to be established to a greater
8 extent by employees with short tenure, and preferably target employees with similarly short but
9 also with longer tenure.

APPENDIX C Extended Goodness-Of-Fit Analysis for the ERG Model

As extended GOF assessment, ERGM allows to evaluate how well the estimated model is able to reproduce not only local network patterns that are of theoretical interest in this research, but also global network characteristics, or general structural features, such as the degree distribution and global clustering of a network (Caimo & Lomi, 2015). In the case of multiplex ERGM, these global network characteristics are assessed for the two networks that are modelled together, here the problem-solving and difficult-tie networks from which dissonant ties emerge. As reported in the results section, the GOF assessment can first be based on t-statistics, computed by comparing observed network characteristics to characteristics simulated based on the fitted model presented in Table 7. T-statistics for the global network characteristics are reported in Table C1.

TABLE C1 Goodness-of-Fit Statistics for Global Network Characteristics

Global network characteristic	Observed	Simulated Mean (SE)		t-statistic
<i>Problem-solving network</i>				
Standard deviation out-degree distribution	10.452	9.792	(0.384)	1.720
Skewness out-degree distribution	2.283	2.394	(0.195)	-0.569
Standard deviation in-degree distribution	9.442	8.315	(0.353)	3.197
Skewness in-degree distribution	1.661	1.456	(0.108)	1.908
Global clustering transitive	0.305	0.267	(0.011)	3.429
Global clustering cyclic	0.142	0.146	(0.010)	-0.348
Global clustering outgoing	0.192	0.182	(0.008)	1.340
Global clustering incoming	0.215	0.213	(0.009)	0.122
<i>Difficult-tie network</i>				
Standard deviation out-degree distribution	3.251	3.162	(0.080)	1.112
Skewness out-degree distribution	2.272	2.272	(0.086)	0.004
Standard deviation in-degree distribution	4.157	4.098	(0.069)	0.857
Skewness in-degree distribution	2.726	2.780	(0.084)	-0.653
Global clustering transitive	0.121	0.126	(0.011)	-0.510
Global clustering cyclic	0.040	0.041	(0.012)	-0.096
Global clustering outgoing	0.076	0.080	(0.008)	-0.557
Global clustering incoming	0.051	0.053	(0.006)	-0.389

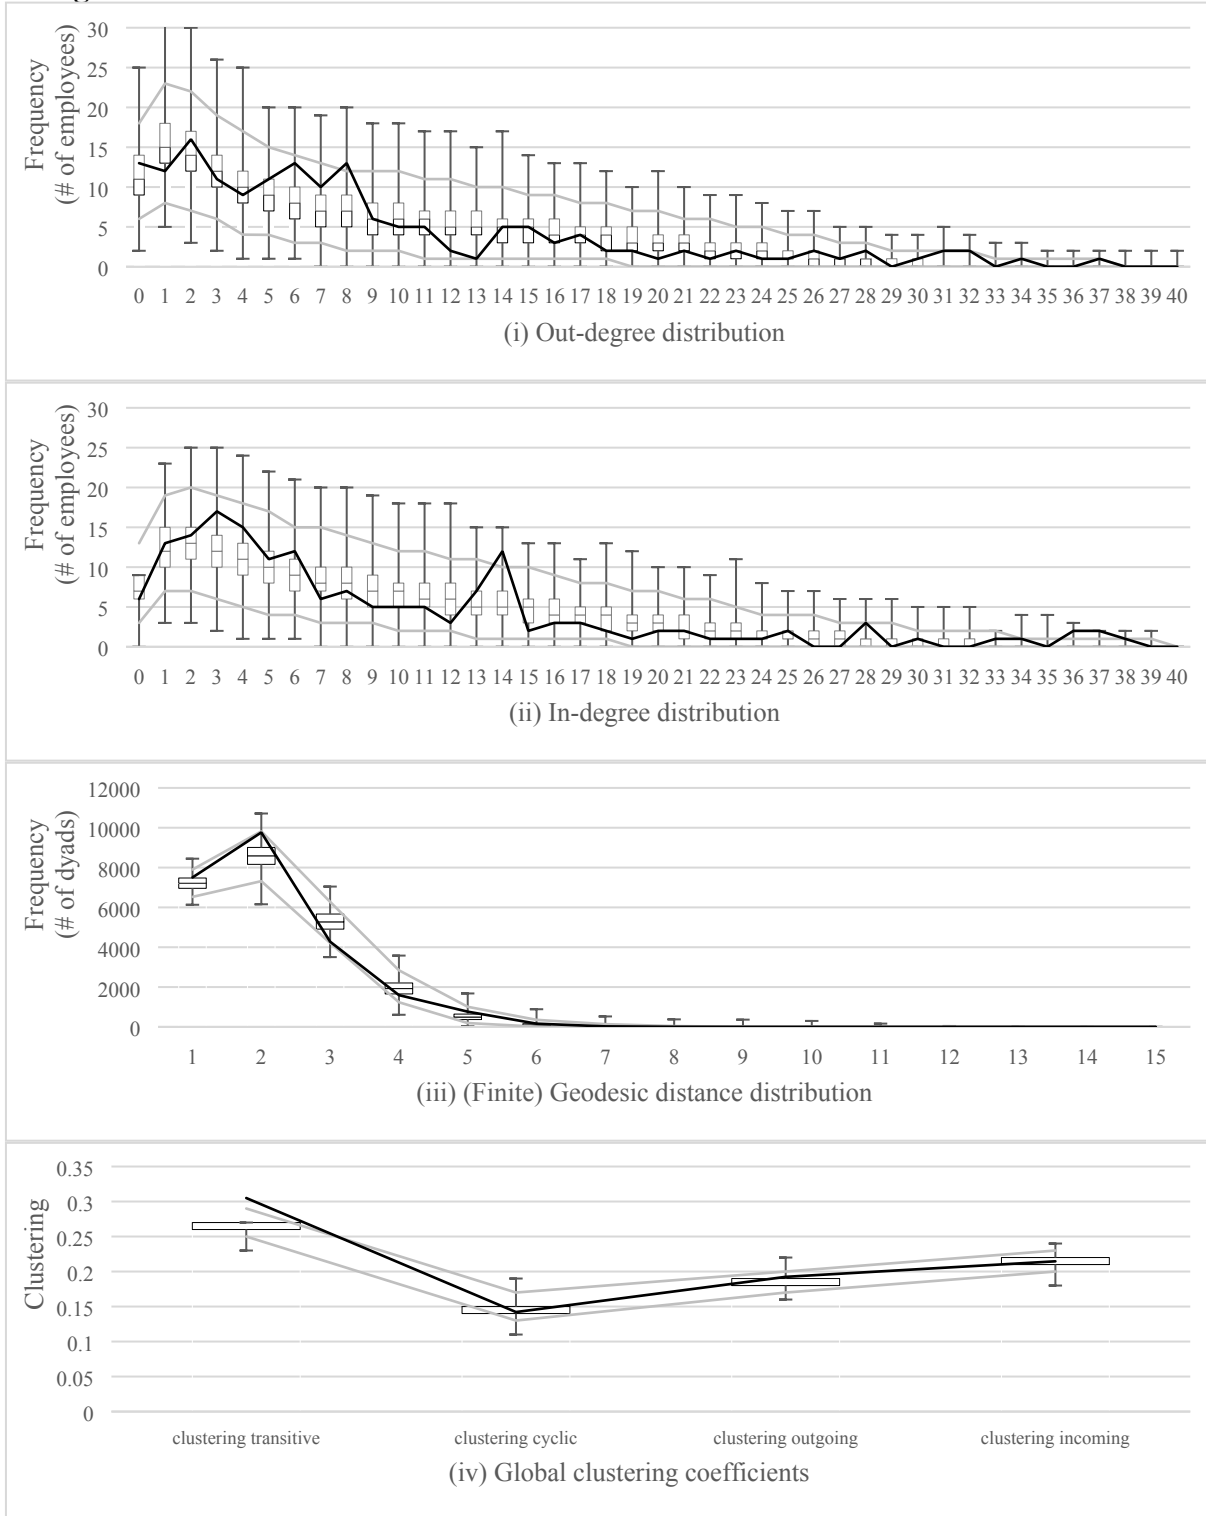

Note. SE = standard error; the different clustering coefficients capture the four possible ways to complete a triangle in a directed network from the perspective of ego (for further details, see Robins et al. 2009).

An inspection of the t-statistics reveals that the values for the standard deviation of the in-degree distribution and global transitive clustering of the problem-solving network exceed the recommended threshold of $|t| = 2$; these global characteristics of the network can, hence, not be reproduced accurately based on the model. Yet, as stressed by Robins and Lusher (2013), it cannot be expected that an ERG model fits all characteristics of an observed network, just as a regression model cannot be expected to explain 100 percent of the variance.

To gain further insights on the global fit characteristics, it is possible to draw sample (i) out-degree distributions—the distribution of outgoing ties for each individual in a network, here egos' number of ties seeking problem-solving assistance and nominating others as difficult to work with; (ii) in-degree distributions—the distribution of incoming ties for each individual in a network, in this case the number of nominations as assistance provider and as difficult to work with that alters receive; (iii) minimum geodesic distance distributions—the distribution of the

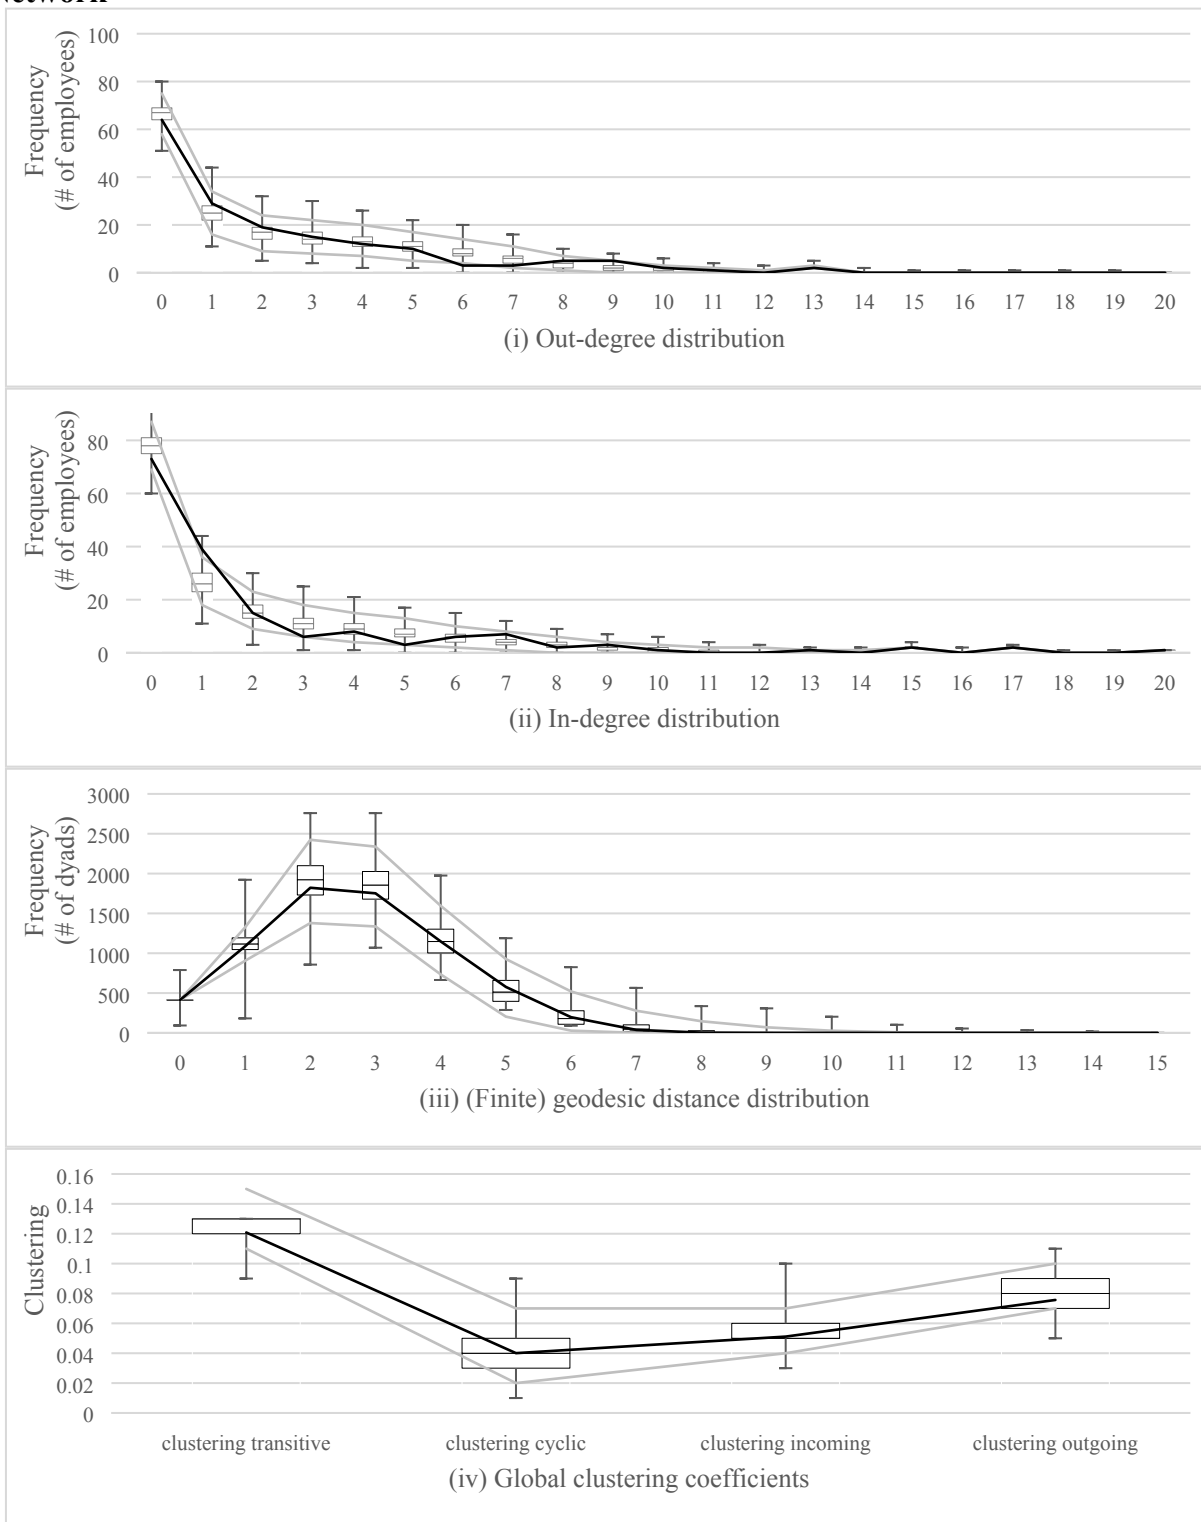

1
2
3 length of shortest path between two individuals; and (iv) global clustering coefficients for the
4 problem-solving assistance and difficult-tie networks and graphically compare the characteristics
5 of these samples to the characteristics of the observed network (see for instance Kim et al., 2016;
6 Robins et al., 2009). These GOF visualizations are shown in Figures C1 and C2 below and allow
7 gaining a visual sense of model GOF. The graphics relating to the problem-solving network in
8 Figure C1 underscore that the model does a relatively good, but not a perfect, job of producing
9 networks that reflect the actual global characteristics of the observed network: The black line that
10 represents the observed network does not in all cases lie within the light-gray lines capturing the
11 range in which 95 percent of simulated networks fall, which would be seen as graphical
12 indication of a perfect fit (Caimo & Lomi, 2015). By contrast, Figure C2 highlights that the
13 difficult-tie network can be reproduced with almost perfect precision from the fitted model.
