## Abstract

As urban areas and land-use constraints grow, there is increasing interest in utilizing urban spaces for food production. Several studies have uncovered significant potential for urban growing to supplement production of fruit and vegetables, focusing on one or two cities as case studies, whilst others have assessed the global scale potential.

Here, we provide a national-scale analysis of the horticultural production potential of urban green spaces, which is a relevant scale for agri-food and urban development policy making using Great Britain (GB) as a case study.

Urban green spaces available for horticultural production across GB are identified and potential yields quantified based on three production options. The distribution of urban green spaces within 26 urban towns and cities across GB are then examined to understand the productive potential compared to their total extent and populations.

Urban green spaces in GB, at their upper limit, have the capacity to support production that is 8x greater than current domestic production of fruit and vegetables. This amounts to 38% of current domestic production and imports combined, or >400% if exotic fruits and vegetables less suited to GB growing conditions are excluded. Most urban green spaces nationally are found to fall within a small number of categories, with private residential gardens and amenity spaces making up the majority of space. By examining towns and cities across GB in further detail, we find that the area of green space does not vary greatly between urban conurbations of different sizes, and all are found to have substantial potential to meet the dietary needs of the local urban population. This study highlights that national policies can be suitably developed to support urban agriculture and that making use of urban green spaces for food production could help to enhance the resilience of the national-scale food system to shocks in import pathways, or disruptions to domestic production and distribution.

**Keywords:** Resilience, Food sovereignty, urban agriculture, Green spaces, Horticultural production potential, Towns and cities

## 1     **1     Introduction**

2     Meeting the dietary needs of growing urban populations in a sustainable manner presents a  
3     significant challenge, particularly under the limitations of decreasing land availability due to  
4     climate change and land degradation, and a need to preserve natural resources and protect  
5     biodiversity. Urbanization can also drive land use change and contribute to the reduction in  
6     available land for agriculture (Satterthwaite et al., 2010, Barthel et al., 2019). Global  
7     projections indicate that by 2100 residential and commercial demand for urban land could  
8     range from approximately 1.1 million to 3.6 million km<sup>2</sup> (Gao and O'Neill, 2020). Urban dwellers  
9     are expected to form 67% of the global population by 2050 (UN Department of Economic and  
10    Social Affairs, 2018), and new urban land will need to be designated to support this trend (Gao  
11    and O'Neill, 2020). These population and land use trends are driving increasing global interest  
12    in incorporating food production into the urban landscape. For example, the intergovernmental  
13    panel on climate change highlights the role of urban agriculture (UA) in climate mitigation  
14    (IPCC, 2018), the Food and Agriculture Organization encourages integrating urban food into  
15    urban planning (Cabannes, 2018, FAO, 2021), and there is increasing recognition that small-  
16    scale food production in urban areas contributes to the sustainable development goals  
17    (Nicholls et al., 2020). Urban agriculture (UA) refers to the production of food in urban and  
18    suburban environments (Orsini et al., 2013, Orsini et al., 2020). Here we focus on urban  
19    horticulture specifically the production of fruit and vegetables.

20    Another major driver of urbanization is the need for food sovereignty, defined as locally held  
21    control over all aspects of the food system, including food markets, natural resources, food  
22    cultures and methods of food production (Wittman, 2011, Lang and Barling, 2012). This has  
23    become particularly apparent with the current COVID-19 crisis as interest in national self-  
24    sufficiency is growing (Garnett et al., 2020) as a way to overcome supply chain disruptions.  
25    The United Kingdom's (UK) food supply is particularly vulnerable to food system shocks like  
26    COVID-19 and Brexit (Lang et al., 2018, Lang and McKee, 2018), as a net importer of food,  
27    with a high reliance on imported fruit and vegetables, including from drought prone countries  
28    (Hess et al., 2016, Hess and Sutcliffe, 2018) to meet a national demand deficit (de Ruiter et  
29    al., 2016). Even more concerning: between 1996 and 2015 fresh fruit and vegetable (FF&V)  
30    imports into the UK almost doubled as shown in data from the Department of Agriculture, Food  
31    and Rural Affairs (DEFRA), and this reliance on imported food (which removes oversight in  
32    food supply), combined with unprecedented political changes and global health challenges in  
33    the UK (which disrupt supplies of imported food and hinder the flow of horticulture workers,  
34    relied upon for the production of local food in GB), place the national food system at risk in  
35    terms of food access and availability. This risk is highlighted by the recent National Food

1  
2  
3 1 Strategy (Dimbleby, 2021). Poor food access and availability are recognized forms of food  
4 2 insecurity (Leroy et al., 2015, Larson et al., 2020).

5  
6  
7 3 A number of recent studies have indicated that the productive potential of urban areas is large  
8 4 and meaningful when compared to food needs. In a global scale analysis, estimates suggest  
9 5 that 25-50% of the UK's urban space could be cultivated to meet the daily recommended  
10 6 intake of FF&V for urban dwellers (Martellozzo et al., 2014). Another study showed that 5-10%  
11 7 of the global production of pulses, roots, tubers, and vegetables could be supported by urban  
12 8 growing (Clinton et al., 2018). A more geographically focused analysis of allotment areas in  
13 9 Sheffield, a large UK city, found that there is more than enough land in Sheffield to support all  
14 10 the FF&V needs of its inhabitants. In their estimates, Sheffield has the potential to support four  
15 11 times the production of commercial horticulture, with significant potential to shorten supply  
16 12 chains and improve food access (Edmondson et al., 2019, Edmondson et al., 2020a). Analysis  
17 13 of another UK city, Leicester, showed that allotment growing is as productive as commercial  
18 14 growing, and just 1.5% of land area there has the potential to produce FF&V for 2.6% of its  
19 15 population (Edmondson et al., 2020a, Grafius et al., 2020). These studies showed that urban  
20 16 agriculture can potentially supplement conventional production and food supply, and that it  
21 17 has a role to play in food systems resilience. However, urban agriculture potential at the  
22 18 national scale has yet to be addressed. This is an important knowledge gap to fill since many  
23 19 of the policies that enable or hinder urban food growing are made at a national level, and this  
24 20 scale is of most relevance within an imports and food system resilience context.

25  
26  
27 21 Food system resilience is the active capacity to continue to achieve goals around food security  
28 22 despite disturbances and shocks (Tendall et al., 2015). These shocks may be economic in the  
29 23 form of increasing land prices, or environmental such as floods and droughts (Misselhorn et  
30 24 al., 2012). Resilience entails building robustness (the ability to withstand disruption), recovery  
31 25 (the ability to quickly 'bounce back') and adaptation (the potential to re-organize) in the system  
32 26 (Ingram, 2017). In this context there is a role for diversifying food import supply chains to  
33 27 withstand sudden supply shocks (Marchand et al., 2016) as a way of contributing to  
34 28 robustness (Kummu et al., 2020), so long as there is not an over-dependence on imported  
35 29 food, which would have the opposite effect in increasing food system vulnerability (Kummu et  
36 30 al., 2020). There are also clear contributions from urban agriculture to 'adaption' in changing  
37 31 farm systems, diversifying food sources and increasing the number of operators (Ingram,  
38 32 2017), to deliver food locally and in a sustained way (Grafton et al., 2015). Although there are  
39 33 challenges to overcome in urban food production i.e. food safety issues, land access and  
40 34 regulatory barriers (Lovell, 2010, Castillo et al., 2013).

1  
2  
3 1 To understand the role that urban agricultural expansion could play in national food  
4 2 sovereignty and resilience, we need a national-scale approach. Whilst local authorities often  
5 3 have significant influence over use of local land resources, many policies critical for the  
6 4 development of UA are made at a national level, including those relating to agricultural  
7 5 production and national food security, the provision of housing, education and priorities for  
8 6 delivering economic development, yet UA is almost absent from this policy scale (Lovell, 2010,  
9 7 Fox-Kämper et al., 2018, Orsini et al., 2020). In this study, we evaluated the horticultural  
10 8 productive potential of urban green spaces across Great Britain and compared this potential  
11 9 to current conventional domestic production and imports to provide an insight into the  
12 10 relevance of urban agriculture for increasing national food self-sufficiency. We also  
13 11 disaggregated this analysis into urban green space categories, and examined a range of  
14 12 towns and cities of varying scales in order to provide insights into where changes to policy and  
15 13 practice could provide the most impact.

## 14 2 Methods

### 15 2.1 *Great Britain as a national scale case study*

16 16 Britain constitutes an interesting national scale case study for this analysis because of its  
17 17 densely populated nature and low self-sufficiency for FF&V, as discussed in the introduction.  
18 18 As a net importer of food it is highly reliant on agricultural imports from the European Union.  
19 19 The UK's self-sufficiency ratio is 61% for all food and 75% for indigenous food (i.e. foods that  
20 20 are traditionally part of UK diets, and are currently or in the past, produced locally). A range of  
21 21 foods are also exported from the UK including high-value, processed products through to low-  
22 22 value products that fail to find a market. The main export markets are Ireland, the United States  
23 23 and France (National Farmers' Union of England and Wales, 2017). Current projections also  
24 24 indicate relatively high rates of urban population growth, with 90% of the UK's population  
25 25 projected to live in urban areas in 2050, in comparison to the European average of 83% (UN  
26 26 Department of Economic and Social Affairs, 2018). This exposes the UK food system to risk  
27 27 of labor shortages in rural locations where agriculture is traditionally located, as well as  
28 28 transport and supply chain disruptions, which would have the negative effect of increasing the  
29 29 price of food or leading to shortages of FF&V.

### 30 2.2 *Estimation of urban green spaces available for horticultural production*

31 31 The urban environment can offer a diverse set of spaces for the expansion of urban growing,  
32 32 including outdoor green spaces, brownfield sites, rooftops and facades, as well as indoor and  
33 33 underground spaces. Here, we focused on the horticultural potential of outdoor green spaces  
34 34 as they have relatively low set-up/retro-fitting costs (barring certain unique crops like apple

1  
2  
3 1 orchards), especially when compared to vertical systems (Eaves and Eaves, 2018); and  
4 2 comparatively easy to access; and can support a diverse range of crops relatively cheaply,  
5 3 without the capital and operating expenses associated with growing substrate, indoor  
6 4 infrastructure and energy accompanying indoor growing (Benke and Tomkins, 2017, Eaves  
7 5 and Eaves, 2018). Furthermore, green spaces currently support, to some degree, the growing  
8 6 of amenity (non-edible) plants, trees and crops. Suitability of outdoor green spaces can also  
9 7 be improved through site additions, such as soil conditioning, raised beds, or polytunnel and  
10 8 glass house construction, the latter being useful for seedling production or year round growing.  
11 9 However, we acknowledge the potential of non-green space growing options, and the inclusion  
12 10 of these would likely increase the horticultural productive potential estimate here substantially,  
13 11 particularly for leafy green vegetables, soft fruit and tomato crops that are well suited to  
14 12 indoor/rooftop environments.

15 13 In an effort to critically review how green spaces are understood in the context of food and  
16 14 plant production and which spaces are regarded as 'usable green space'; we note that Kabisch  
17 15 and Haase (2013) broadly regard green spaces as any vegetation found in the urban  
18 16 environment, which include parks, open spaces, residential gardens, or street trees. They also  
19 17 recognize the potential to create green spaces in 'non-green spaces' through demolition of  
20 18 building and artificial structures, de-sealing of soils and re-use of brownfield sites. Daniels et  
21 19 al. (2018) recognize that green spaces may differ in their extent of natural and artificial  
22 20 elements, and therefore their benefits from a multidimensional perspective should be  
23 21 considered cautiously. In their analysis Tyrväinen et al. (2007) showed that green space  
24 22 classifications are strongly influenced by social perceptions. A comprehensive review  
25 23 (Rupprecht et al., 2015) showed that certain green spaces (e.g. naturally vegetated spaces or  
26 24 highly managed spaces), although receiving more attention were not the only types of green  
27 25 spaces. They found an absence of a formal definition of green spaces and instead a myriad  
28 26 of typologies or 'hybrid states' to categorize green spaces that can be based on land tenure,  
29 27 conservation, maintenance regimes, use, regulation, and legitimacy. This is thought to make  
30 28 the definition of green spaces overwrought with uncertainty (McLain et al., 2014).

31 29 In our analysis we used a data set at the scale of Great Britain (England, Wales and Scotland)  
32 30 that encompassed green spaces with both artificial and natural elements (see:  
33 31 <https://www.ordnancesurvey.co.uk/xml/codelists/OpenFunctionValue.xml>). We considered all  
34 32 green spaces as potentially suitable spaces for urban agriculture, unless they were water  
35 33 bodies, foreshores or beaches. This was regarded on the basis that artificial elements could  
36 34 be removed, surfaces unsealed, buildings demolished or brownfield sites reclaimed (Kabisch  
37 35 and Haase, 2013). This OS Master Map Green space product (Ordnance Survey, 2017) was  
38 36

1  
2  
3 1 used to delineate urban green spaces across the UK. The areal limits of this dataset only  
4 extend to the countries of Great Britain, thus we constrained our analysis to these countries.  
5 2  
6 3 This dataset categorizes the natural environment in major urban areas across both public and  
7 private spaces and uses the British National Grid (BNG) spatial reference system to describe  
8 4 the easting and northing coordinates of urban green spaces in units of meters. The Master  
9 Map Green space Layer is made up of a subset of the Topographic Area polygons from OSMM  
10 6 Topography Layer identified by a unique identifier (TOID). Each polygon (land parcel) has  
11 7 been assigned a primary function and form and, in certain cases, secondary functions and  
12 8 forms. This initial dataset, imported into ArcGIS Pro comprised 33,354,035 rows of data across  
13 9 several attribute tables. After filtering to remove water bodies (inland water, foreshores and  
14 10 beaches) seen as spaces unsuitable for urban growing, the data was exported as .csv files  
15 11 and merged into a MySQL database for data cleaning. Duplicates were searched by  
16 12 generating data queries against the unique TOID to remove identical rows of data and a final  
17 13 dataset for analysis was produced (see load-log provided as supplementary data).  
18 14

19 15 In the final dataset, 18 categories remained of green space suitable for outdoor urban  
20 16 horticulture from the OS data, based on their primary function categorization (Figure 1).  
21 17

### 22 17 2.3 *Quantification of potential urban horticultural production*

23 18 Selecting crops for urban agriculture is influenced by a wide range of factors including  
24 19 considerations of land and soil suitability, requirements in terms of crop inputs and labor  
25 20 (McDougall et al., 2019, Edmondson et al., 2019, Lal, 2020). In this study, we used current  
26 21 domestic horticultural production as a representative guide to the crops that are both relatively  
27 22 suited to the biophysical growing conditions of GB and the food preferences of its residents.  
28 23 Hence, to produce a shortlist of crops for inclusion we analyzed data from UK Horticulture  
29 24 statistics from DEFRA (2019). This yielded six main FF&V categories: (i) orchard fruit, (ii) soft  
30 25 fruit, (iii) roots and onions, (iv) brassicas, (v) legumes, and (vi) others (including peppers and  
31 26 salad greens), which we included in our analysis (Table 1). We acknowledge that certain soil  
32 27 and climate factors can make areas more suited to particular crop categories. However, in  
33 28 urban settings, conditions can be more easily manipulated through the use of physical barriers  
34 29 against wind, hail and pest damage or the use of rain water harvesting in water supply; hence,  
35 30 we maintain this simple assumption that these would be the main crop types produced.  
36 31

37 31 <INSERT TABLE 1 ABOUT HERE>

38 32 We explored three options (Table 2) for the allocation of growing space to the six crop  
39 33 categories: a) an equal split where each polygon was divided equally between the six FF&V  
40 34 categories described above (Total production per land allocation was described as the "Equal-

1 Split option”); b) a split proportionate to domestic production, where each polygon was divided  
2 to match the area of land currently under commercial FF&V production in the UK, as reported  
3 by DEFRA (2019) (breakdown by crop category was described as the “Domestic-Production  
4 option”), and c) a split based on economic value where each polygon was divided according  
5 to the crop value of each crop category in the DEFRA (2019) dataset. Scenario a), then,  
6 represents the baseline option, scenario b) assumes that UA crops would be shaped by similar  
7 market, policy and biophysical conditions that conventional horticulture growers experience,  
8 and c) assumes that high value crops are more desirable as they can be sold at a premium  
9 price so more are grown, but all crops are still included for diversity of production (breakdown  
10 by economic value was described as the “Price-Value option”).

11 <INSERT TABLE 2 ABOUT HERE>

12 We assumed production in these areas would be equivalent to the national domestic average  
13 as indicated by the DEFRA statistics to estimate the yield per area for outdoor urban green  
14 spaces. Using data from a 20-year period (1996-2015), we summarized the yields for the six  
15 crop categories per unit area of land (Table 1). We averaged this over 20 years to remove  
16 year-on-year variability, after first examining the data trends to ensure there were no  
17 substantial systematic changes in productivity over the 20-year period. Likewise, we tabulated  
18 the average value for each of these crops, per unit area.

#### 19 *2.4 Estimating the relevance of urban horticultural production to national FF&V self-* 20 *sufficiency*

21 In order to estimate the relevance of potential urban horticulture to national scale food system  
22 resilience, we compared the yield estimates as described in 2.3 to the quantity of food  
23 imported into the GB. In line with our production estimate methodology, we used DEFRA’s  
24 2019 horticulture data on imports for the same time period (2006-2015) and organized these  
25 data into the same six broad crop categories described above. Where there were FF&V  
26 categories that did not correspond to the six domestic crop categories (e.g., avocados,  
27 bananas, grapes, and sweet potatoes) we included these into exotic fruit and exotic vegetable  
28 categories. They represented imports that were not suitable for GB production at scale, but  
29 are nonetheless important contributors to overall supply of FF&V.

30 Next, to understand how much food could be produced if all green spaces were substituted  
31 for urban agriculture, the total horticultural productive potential under three options for sub-  
32 allocation of crops (Table 2) in urban green spaces were calculated, as described in section  
33 2.3.

## 1 2.5 *City-scale comparison of horticultural productive potential*

2 To examine the distribution of urban green spaces within small, medium and large urban towns  
3 and cities across GB and understand the productive potential compared to their total extent  
4 and populations, green spaces were extracted within the boundaries of major cities, towns  
5 and settlements in England, Wales and Scotland at 26 locations. These represented different  
6 climate and socio-economic areas of GB, and excluded London which was regarded to be an  
7 anomaly due to its population size. We summarized the green spaces and horticultural  
8 productive potential within the boundaries of these GB towns, and compared these to  
9 population sizes for these settlements (Office National Statistics, 2019), in order to explore the  
10 degree to which urban areas have differing green space characteristics and urban horticultural  
11 production potential. To generate a figure of yield potential under the "Equal-Split" option, we  
12 divided total yield across the green spaces by population size, providing an estimate of yield  
13 per person in kilograms.

14 The boundaries for England and Wales were defined using the Major Towns and Cities dataset  
15 from the Office of National Statistics, and the Settlements shape file from the National Records  
16 (NRS) was used for Scotland (Table 3). Towns and cities were categorized into small, medium  
17 and large cities and shown in Figure 3 based on their population and area size.

18 <INSERT TABLE 3 ABOUT HERE>

## 19 **3 Results**

### 20 *3.1 Urban green spaces available for horticultural production*

21 Figure 1 provides a breakdown of the types of urban green space in GB, showing the total  
22 number of land parcels along with mean parcel sizes. These data highlight that more than half  
23 of these urban green spaces were contained in just two categories: private gardens (34%) and  
24 amenity areas for residential or business purposes (23%) (percentages in Figure 1a).  
25 Allotments or community gardens, that are currently managed as productive spaces for urban  
26 agriculture within the urban framework of towns and cities, make up about 1% of urban green  
27 space nationally.

28 The data also highlighted that whilst private gardens made up the largest total area, this area  
29 comprised many relatively small spaces (Figure 1b). Recreational spaces and parks tended  
30 to have much greater mean areas per land parcel, and in total, they contributed to a moderate  
31 proportion (>10%) of the total GB green space.

32 <INSERT FIGURE 1 ABOUT HERE>

1  
2  
3 1 *3.2 Potential production of FF&V in urban green spaces at GB scale compared with*  
4 *conventional domestic production and imports*  
5  
6

7 3 A similar total tonnage of FF&V is produced under all three crop-allocation options, but with  
8 differences in the production for each category of FF&V (Table 2). At its upper limit, we  
9 estimated that urban green space could support production of 20.70 –22.41 metric tons (MT)  
10 of FF&V per year in GB, if all urban green spaces were utilized and expected average crop  
11 yields were achieved. This compared with total average annual domestic production of 2.89  
12 MT and imports of 56.40 MT. Hence, the estimates for potential urban production equated to  
13 35–38% of total domestic production and imports. Comparing only the categories of FF&V that  
14 are suitable for production in GB (i.e., excluding exotic FF&V categories), then our estimates  
15 indicated that urban green space could produce between 3.8–4.1x the total FF&V produced  
16 domestically (Table 2). Examining the production estimates on a crop category basis (Figure  
17 2b), the total production potential for each crop sub-allocation option exceeded imports and  
18 domestic production, apart from exotic FF&V categories, which are purposefully excluded from  
19 the urban production estimates. Results of this analysis are presented in Figure 2.

31 17 *3.3 Variation in green space and in horticulture productive potential per capita between*  
32 *cities across GB*  
33  
34

35 19 We found that total productive green space area as a proportion of the total urban land area  
36 varied between 43–57% across the selected locations (Table 4). By including the population  
37 data of towns and cities, and quantifying the amount of food that could be produced under the  
38 “Equal-Split Option” we estimated productivity per person varied between 171–281 kg per  
39 annum across towns and cities (Table 4). When this is compared to the recommended daily  
40 intake of fresh fruit and vegetables, recommended by the WHO and FAO (400g/day or  
41 146kg/y), we determine that if all green space was committed to urban growing, local residents  
42 could produce more than enough FF&V to meet their personal dietary requirement.  
43  
44  
45  
46  
47

48 27 <INSERT TABLE 4 ABOUT HERE>  
49  
50

51 28 In our subset of 26 GB towns and cities (Figure 3), we found that private gardens, which are  
52 the most abundant green space category, vary as a percentage of productive green space  
53 between 41–69% of green space, with the Scottish towns and cities (Aberdeen, Edinburgh  
54 and Stirling) tending to have less space attributed to private gardens. In this subset of GB  
55 towns and cities; amenity and residential areas make up between 8–22% of green spaces and  
56  
57  
58  
59  
60

1  
2  
3 1 allotments and community gardens make up between 0–2.6% of green space, and this looks  
4 2 slightly different to the national picture.

#### 10 4 **4 Discussion**

11  
12 5 This study presents the first national level assessment of horticulture productive potential in  
13 6 urban green spaces, providing evidence that may support the adoption of urban horticulture  
14 7 as a tool to increasing national food self-sufficiency, which may in turn build system resilience  
15 8 and food sovereignty. One way urban food growing contributes to food system resilience  
16 9 (Olsson et al., 2016) is by enhancing food production as part of multifaceted urban land use,  
17 10 and this in-turn re-couples agriculture to the regional food system. This can happen through  
18 11 incentives and spatial planning to access urban land, provision of local food markets, and  
19 12 networks to link supply chain actors. There are however challenges relating to production  
20 13 inefficiencies, labor and resource use (McDougall et al., 2019). These will need to be  
21 14 addressed in ensuring UA becomes a viable diversification option for food production. For  
22 15 example, social sustainability tends to be low due to the seasonal, temporary nature of  
23 16 agricultural work (Mitaritonna and Ragot, 2020) which may lead to poor rights and participation  
24 17 of workers (Molinero-Gerbeau et al., 2021). There are also food safety risks from pesticides  
25 18 and heavy metal pollutants in urban environments (Mok et al., 2014, McDougall et al., 2019).

26  
27  
28 19 This national scale case study addresses a current research and policy gap (Fox-Kämper et  
29 20 al., 2018, Orsini et al., 2020) by carrying out an analysis relevant to the scale of national policy  
30 21 making. This is timely, as the UK's food system has come under pressure from political, health  
31 22 and labor issues in recent times (Schramski et al., 2019, Garnett et al., 2020), motivating  
32 23 governments and society to reconsider where and how food is produced in the UK. While  
33 24 issues around food insecurity and disruptions to food supply are heightened in the UK by  
34 25 reliance on imports, urbanization, COVID-19, and Brexit, the UK is not an exclusive case.  
35 26 Some studies have shown increasing concern for disruptions to national food supply chains  
36 27 and knock on impacts to food production cycles (e.g. Brazil, the Middle East) and price  
37 28 volatility (e.g. South Africa), and even household food insecurity (e.g. China) (Pu and Zhong,  
38 29 2020, Devereux et al., 2020) .

39  
40  
41 30 The spatial analysis of urban green spaces at the national level revealed that over half of  
42 31 green spaces in urban areas are made up of private gardens and privately-held land used for  
43 32 amenity gardens, with only a small fraction ~1% of green space currently being used formally  
44 33 for food growing (i.e., allotments and community gardens). This finding suggests that if  
45 34 expansion of urban agriculture was to be implemented as a national priority, instruments that

1  
2  
3 1 promote and enable food growing in private spaces and households would be important to  
4 2 consider. Although this would need to take heed of the organizational differences of UA in  
5 3 terms of beneficiaries, distribution channels and actors (i.e. self-growing / socio-cultural /  
6 4 commercial) (Krikser et al., 2016). This could constitute the provision of incentives to  
7 5 incorporate sufficient growing space into new residential developments, offering tax rebates  
8 6 or growing subsidies to property owners who engage in, or allow the use of, urban land parcels  
9 7 for urban growing, as well as education schemes, advice networks, and campaigns targeting  
10 8 urban growers specifically (e.g., an extension of 'Dig for Britain', 'Pick for Britain' or 'Clap for  
11 9 the NHS'). The latter would also address the risk of agricultural supply disruptions due to labor  
12 10 shortages across rural and urban locations. However, incentivizing production in private  
13 11 spaces may exacerbate social inequities, as this is an opportunity only available to those with  
14 12 space. If public money is used, the mechanisms by which food produced privately could  
15 13 produce public goods would be important to consider.

14 14 However, a case could also be made that publicly held green spaces, such as parks, might  
15 15 be attractive options to local authorities for supporting urban food growing activities given that  
16 16 these spaces are more likely to be in their direct control. Consistent declines in funding due to  
17 17 austerity measures has significantly decreased national budget allocations to local councils  
18 18 across Britain, impacting their budget to manage green space, and this has already  
19 19 encouraged individuals and communities to take on an increased responsibility for local  
20 20 services (Whitten, 2019). Furthermore, the larger land parcel sizes of parks mean that they  
21 21 may provide more space to accommodate growing projects at scale (particularly for social or  
22 22 commercial enterprises), with less likelihood of light shading drawbacks and a better  
23 23 concentration of resources (e.g., skilled labor or transport), which may pose a challenge where  
24 24 sites are smaller and more dispersed in a city.

25 25 Our analysis suggests that urban green space at the GB level has the capacity to support  
26 26 production of nationally significant volumes of FF&V, helping to re-orient food systems to  
27 27 produce more food locally, increase food sovereignty and support food system resilience.  
28 28 These estimates of horticulture productive potential should be considered as being near to the  
29 29 extreme upper limit for production in GB urban green spaces where all space is utilized well,  
30 30 growers have sufficient skills, knowledge and resources to support effective production, and  
31 31 growing conditions are suitable (e.g. climate, soil, light, etc.). In reality, realizing this productive  
32 32 potential is contingent on uptake of urban growing by local stakeholders, ease of access to  
33 33 green spaces and resource supports in the form of finance, knowledge and institutional capital  
34 34 (Schupp et al., 2016, Mead et al., 2021b). Nonetheless, our results indicate that further  
35 35 consideration of urban green spaces as potential contributors to meaningful levels of FF&V

1  
2  
3 1 supply at a national scale are warranted. For example, even if only a small percentage of this  
4 2 area is agronomically suitable and available, this could still represent a substantial contribution  
5 3 to national supplies of FF&V.  
6  
7

8  
9 4 This national scale assessment also allowed for an estimate of current levels of urban FF&V  
10 5 production in spaces devoted to food growing. We estimated that the space dedicated to  
11 6 allotments and community growing across GB may currently support production of FF&V  
12 7 equivalent to ~0.01% of domestic commercial production. Urban production of FF&V is likely  
13 8 to be higher than this figure as this neglects growing undertaken in private residential settings,  
14 9 institutional grounds, and other settings. Other smaller scale studies have shown that 1.5% of  
15 10 allotment land can support 3% of the fresh food needs of an urban population (Edmondson et  
16 11 al., 2020b).  
17  
18  
19  
20  
21

22 12 We also analyzed and mapped the food production potential across small, medium, and large  
23 13 cities to provide a better understanding of how productive potential might vary across urban  
24 14 centers nationally, and how potential might compare to the size of local populations where  
25 15 locally grown FF&V is more likely to be consumed (Figure 3, Table 4). We found that total  
26 16 green space area as a proportion of urban extent varied by 12% across the locations selected,  
27 17 and this variation did not appear to be systematically related to town or city size (in terms of  
28 18 land area footprint) (Table 4). This is in contrast to the findings of Martellozzo et al. (2014) in  
29 19 their global scale analysis that suggested smaller towns, which are more abundant, would  
30 20 have greater potential for urban growing.  
31  
32  
33  
34  
35  
36  
37

38 21 Whilst productive potential varied across the urban conurbations studied here, they were all  
39 22 relatively high compared to the dietary needs of the local population. Productivity per person  
40 23 could be as high as 281 kg per annum which is a substantial volume of food per person in  
41 24 dietary terms. By comparison, the Food and Agriculture Organization (FAO) and World Health  
42 25 Organization (WHO) recommend adults consume a minimum of 400 g of fruit and vegetables  
43 26 per day (FAO and WHO, 2019), equating to 146 kg per year. By our calculation, productivity  
44 27 per person could be as high as 1.9 x the recommended yearly fruits and vegetables  
45 28 consumption per person per year (at 281 kg). The estimated upper limit for FF&V production  
46 29 per person in all the locations studied was in excess of this annual recommendation. From a  
47 30 national governance perspective, the town/city scale analysis presented here suggests that  
48 31 policies and mechanisms for incentivizing FF&V growing are likely to be valuable across small,  
49 32 medium and large cities alike and national level approaches could be suitable in the GB  
50 33 context.  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 1 In addition to national scale resilience of FF&V supply, increasing urban agriculture may confer  
4 2 additional benefits, directly through the provision of ecosystem services (e.g., climate  
5 3 regulation, sequestration benefits), and indirectly by improving well-being, through diet quality  
6 4 and connection to nature (Clinton et al., 2018, Kingsley et al., 2021, Mead et al., 2021a, Evans  
7 5 et al., under review). Furthermore, because the scale of production in urban agriculture is often  
8 6 small, FF&V tend to be sold or consumed locally, and this contributes to local food production  
9 7 and resilience, replacing purchases of imported food. This is known as import substitution  
10 8 (Rodrigues, 2010, Ershova and Ershov, 2016). Although import substitution, as a development  
11 9 theory, promotes productivity and economic gains at a national level, Bellows and Hamm  
12 10 (2001) showed that import substitution can promote local autonomy and sustainable  
13 11 development at a localized food system level, and this proximity to urban agriculture may in-  
14 12 turn encourage positive dietary behaviors in local people (Mead et al., 2021a).

#### 23 13 4.1 *Limitations*

24 14 This analysis made assumptions in order provide a simple, nation-wide basis for estimation of  
25 15 yields. However, we acknowledge that there are limitations to the approach as yields will rely  
26 16 on climatic factors, nutrient availability, soil type, access to light, pest and disease pressure  
27 17 and grower skill levels which have not been considered in our analysis. From this perspective,  
28 18 our analysis of horticulture productive potential may be considered an upper-estimate.

29 19 Our predictions also assumed that urban growers are capable of achieving the same yields  
30 20 as conventional growers. This is could be viewed as a limitation, however, this assumption  
31 21 aligns with studies showing that urban horticultural production systems may yield higher than  
32 22 commercial field settings (Edmondson et al., 2020a, McDougall et al., 2019, Kingsley et al.,  
33 23 2021), due in part to land management approaches which enhance ecosystem service  
34 24 provisions and improve soil quality (Edmondson et al., 2014). Urban horticultural production  
35 25 environments such as allotments may have a greater input of manual labor hours which when  
36 26 combined with complementary cropping can facilitate “over-yielding” (McDougall et al., 2019).  
37 27 Yet alternative evidence (Cook et al., 2012) suggests that yields may be lower in allotment  
38 28 settings with a greater diversity of crops.

39 29 As the study focuses on yield as a measure of productive potential, we also do not consider  
40 30 the infrastructure requirements post-production. For example, storage and processing  
41 31 facilities would be needed to accommodate increased production, and would help avoid post-  
42 32 harvest loss and improve availability throughout the year.

43 33 In a food production context Krikser et al. (2016) highlight that there may be different  
44 34 typologies of UA related to form and function, and their characteristics of space, market

1  
2  
3 1 orientation, financing, products and activities. They identify these dimensions of UA as self-  
4 2 supply, socio-cultural or commercial. We do not attempt to address horticultural production at  
5 3 this level of complexity, as it appears more suited to analysis at a more local (e.g. city) scale.  
6  
7  
8

## 9 4 **5 Conclusion**

10 5 This study provided the first national scale analysis of the role that expanding urban agriculture  
11 6 in green spaces could play in increasing both the production of fresh fruit and vegetables, and  
12 7 national food system resilience and sovereignty. We found that urban green spaces are  
13 8 substantially underutilized for urban food production, with opportunities for coordinated  
14 9 campaigns and financial incentives to stimulate the productive utilization of urban land as a  
15 10 resource for food production. The presence of publicly held land within the urban green space  
16 11 network in the form of amenity gardens managed by local councils could play a crucial role in  
17 12 building knowledge and social capacity for urban agriculture. With allotments and community  
18 13 gardens already supporting a network of committed and knowledgeable gardeners, a rich  
19 14 source of knowledge and skills is already present in urban areas which can be leveraged to  
20 15 provide technical support to other members of the public, as a way of encouraging  
21 16 engagement in urban growing. The relative homogeneity of urban green spaces across towns  
22 17 and cities of different land and population size, suggests that urban agriculture potential is  
23 18 independent of demographic and economic factors, and that if only a proportion of the  
24 19 population engage in urban agriculture, the productive output in terms of meeting healthy  
25 20 dietary guidelines could be significant. This provides another avenue for national policy  
26 21 makers to achieve efforts to tackle diseases like obesity, diabetes, and heart disease, while  
27 22 addressing systemic issues like household food poverty in the process. This evidence  
28 23 suggested that as well as an environmental incentive to the uptake of urban growing, there  
29 24 may be an economic and social motivation for supporting urban agriculture.

1 List of Figures  
a)

b)

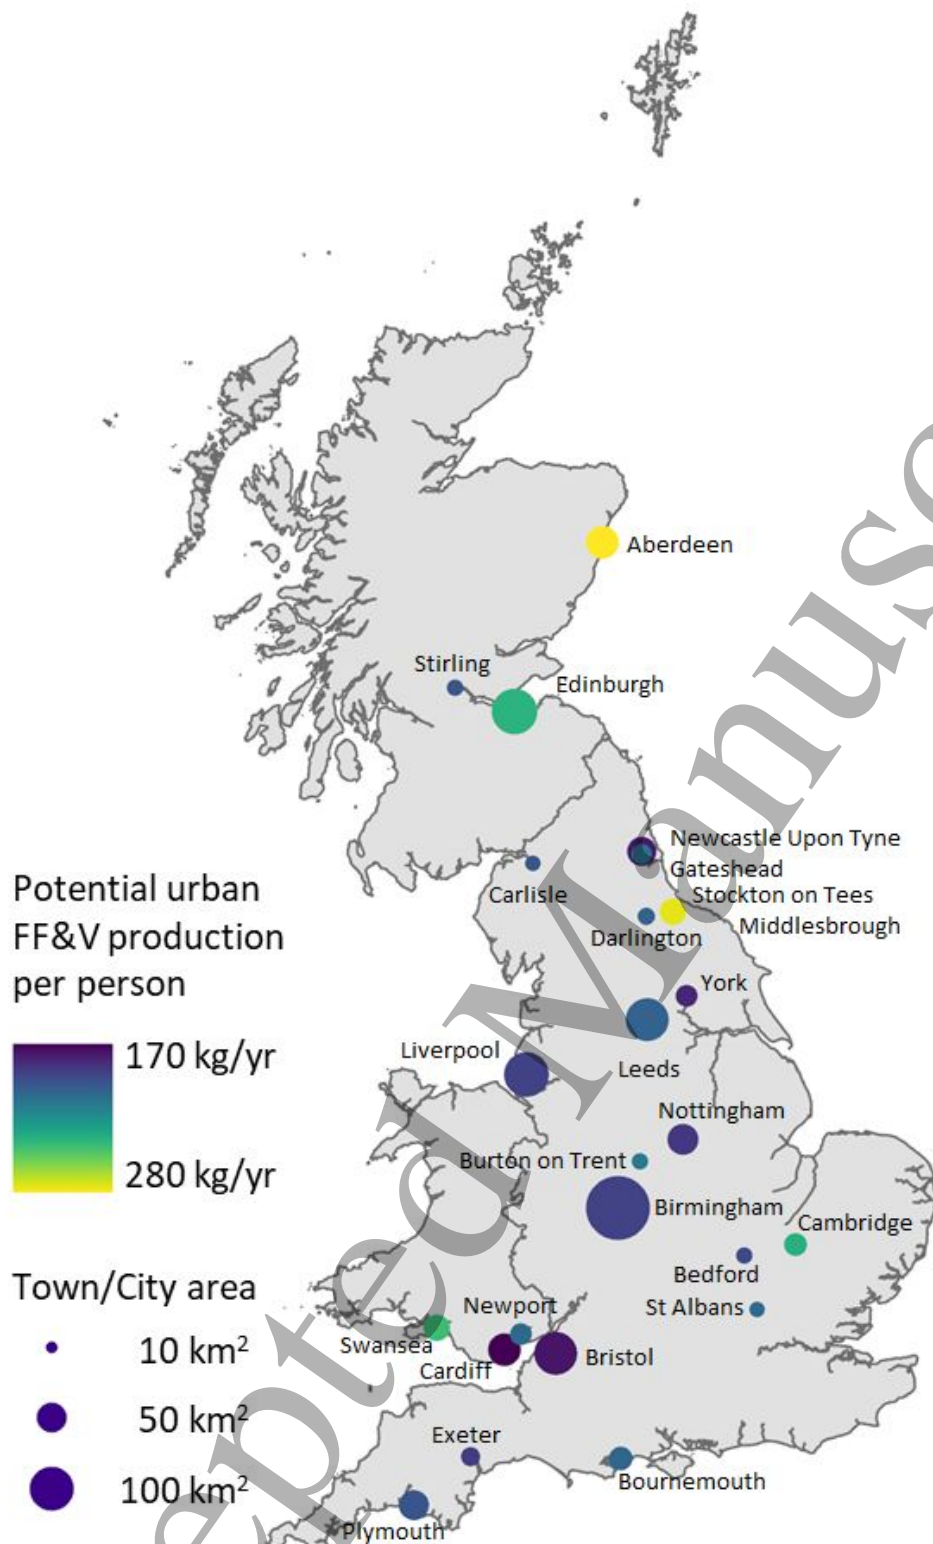

**Figure 1:** Characteristics of green space in Great Britain. a) Comparison of the green spaces in GB by total area and as a cumulative percentage of the total green space area (in km<sup>2</sup>) across England, Wales and Scotland. b) Total number of land parcels in each category and their mean area (in m<sup>2</sup>).

**Figure 2:** Estimated national production potential of fresh fruit and vegetables expressed as metric tons per year (MT/y) for GB green spaces compared with domestic production and imports. Section 2.3 further described that estimates were based on 3 options. a) Total production per land allocation: Equal-Split option. b) Breakdown by crop category: Domestic-Production option. c) Breakdown by economic value: Price- option

3  
4  
5

**Figure 3.** The location of 26 Great Britain towns and cities analysed for their urban fresh fruit and vegetables (FF&V) production expressed as kg per year (kg/y) in relation to town and city size.

1  
2  
3 **List of Tables**  
4  
5

6 **Table 1:** Categories of Fresh Fruit and Vegetables (FF&V) produced in the UK classified in  
7 line with DEFRA horticulture categories (DEFRA, 2019), calculated as 20-year average output  
8 in tons per hectare (T/ha), area devoted to production (ha) and value (£ /ha).  
9

FF&V categories (Total)	Mean domestic production, T/ha	Area, ha	Area as a % of total	Value, £ Million/ha
Orchard Fruit	17	19,983	12%	0.0066
Soft fruit	11	8,954	6%	0.0279
Roots & Onions	45	29,648	18%	0.0086
Brassicas	17	29,879	19%	0.0065
Legumes	4	55,125	34%	0.0014
Others	21	17,026	11%	0.0135

**Table 2:** Fresh fruit and vegetable (FF&V) production in metric tonnes per year (MT/y) under different production options and 20 year average domestic production and imports.

FF&V Categories	Urban greenspace production potential (MT/y)			Domestic Production (MT/y)	Import (MT/y)	Domestic + Imports (MT/y)
	EQUAL	DOMESTIC	PRICE			
Orchard Fruit	3.313	2.385	1.988	0.341	0.791	1.132
Soft fruit	2.144	0.772	5.531	0.102	0.061	0.163
Roots & Onions	8.770	9.471	6.841	1.334	0.356	1.690
Brassicas	3.313	3.777	1.988	0.508	0.172	0.680
Legumes	0.780	1.590	0.094	0.234	0.042	0.276
Others	4.093	2.701	5.157	0.365	1.168	1.534
Exotic Fruit	-	-	-	-	47.825	47.825
Exotic Veg	-	-	-	-	5.989	5.989
<b>Total FF&amp;V</b>	<b>22.412</b>	<b>20.697</b>	<b>21.597</b>	<b>2.885</b>	<b>56.404</b>	<b>59.290</b>

1 **Table 3:** Datasets and format used in the geographical information system analysis.

Dataset	Format
UK Horticulture statistics, 2019. Department of Environment, Food and Rural Affairs	Excel Spreadsheet
Ordnance Survey, 2019. OS Master Map Greenspace, Accessed from Digimap.edina.ac.uk	Geography Mark-up Language (GML)
Major Towns and Cities, 2015. Accessed from Office of National Statistics	Shape file
Settlements, 2016. Accessed from NRScotland.gov.uk	Shape file

**Table 4:** Summary of population size, land area (km<sup>2</sup>), green space (km<sup>2</sup>), calculated productive potential for fresh fruit and vegetables (FF&V) in metric tonnes (MT) and productivity per person in kg for 26 Great Britain (GB) towns and cities, based on the Equal-Split option. Town size classification based on population size: Large>500,000, Medium >100,000, Small<100,000

Size classification based on population size	GB Town or City	Country	Population size	Total Area in km <sup>2</sup>	*Green Area in km <sup>2</sup>	Total Productive Potential for FF&V (MT)	Potential Productivity of FF&V per person (Kg)
Large	Birmingham	England	1,160,254	229.13	126.01	224.3	192.2
Large	Edinburgh	Scotland	524,930	125.11	71.79	127.8	242.1
Large	Liverpool	England	586,889	123.31	63.74	113.4	192.2
