Previous research investigated cross-modal influence of olfactory stimuli on perception and evaluation of faces. However, little is known about the neural dynamics underpinning this multisensory perception, and no research examined perception for images of oneself, and others, in presence of fragrances. This study investigated the neural mechanisms of olfactory-visual processing using electroencephalography (EEG) and subjective evaluations of self- and other-images.

22 female participants evaluated images of female actors and themselves while being exposed to the fragrance of a commercially available body wash or clean air delivered via olfactometer. Participants rated faces for attractiveness, femininity, confidence and glamorousness on visual analogue scales. EEG data was recorded and event-related potentials (ERPs) associated with onset of face stimuli were analysed to consider effects of fragrance presence on face processing, and interactions between fragrance and self-other image-type.

Subjective ratings of confidence, attractiveness and femininity were increased for both image-types in pleasant fragrance relative to clean air condition. ERP components covering early-to-late stages of face processing were modulated by the presence of fragrance. Findings also revealed a cross-modal fragrance-face interaction, with pleasant fragrance particularly affecting ERPs to self-images in mid-latency ERP components.

Results showed that the pleasant fragrance of the commercially available body wash impacted how participants perceived faces of self and others. Self- and other-image faces were subjectively rated as more attractive, confident and feminine in the presence of the pleasant fragrance compared to an un-fragranced control. The pleasant fragrance also modulated underlying electrophysiological activity. For the first time, an effect of pleasant fragrance on face perception was observed in the N1 component, suggesting impact within 100 ms. Pleasant fragrance also demonstrated greater impact on subsequent neural

59 processing for self, relative to other-faces. The findings have implications for understanding  
60 multisensory integration during evaluations of oneself and others.

61

## 62 1.1 Introduction

63

64 There is a well-established link between self-confidence, self-esteem and self-perceived  
65 physical attractiveness, which appears to be particularly robust in women [1,2]. Fragrance  
66 has historically been used across cultures to influence a person's appearance and  
67 attractiveness [3]. Research has demonstrated the interaction between the olfactory system  
68 and other sensory systems such as vision, which creates a unified, meaningful multisensory  
69 experience [4]. The presence of odours can provide important contextual or social cues  
70 which influence perception of various stimuli via cross-modal multisensory perception [5].  
71 For example, pleasant fragrances can enhance the perceived pleasantness of a virtual  
72 reality environment [6], as well as people's perception of art [5], and perception of face  
73 images [3,7–12]. These effects are bi-directional; positively or negatively valenced images  
74 influence perception of fragrances [13] and congruent visual stimuli can enhance fragrance  
75 detection sensitivity [14].

76

77 Research has begun to elucidate the cross-modal and multisensory impact of olfactory  
78 stimuli on perception of faces. Spence [15] highlights the widespread nature of these effects  
79 with the observation that a variety of fragrances have been shown to alter face perception,  
80 with significant implications for affective responses and social interactions. In a recent  
81 review, Syrjänen et al. [16] conclude that, despite some conflicting findings, the evidence  
82 suggests that positive or negative fragrances influence face perception in the direction of  
83 valence (i.e., pleasant fragrance increases positive evaluations of faces). Again, fragrance-  
84 face cross-modal multisensory perception occurs in a bi-directional fashion, amplifying the  
85 intensity of each stimulus; for example, fragrances were rated as more pleasant when paired  
86 with a happy, compared to a disgusted face in [12].

87

88 Similarly, the cross-modal influence of fragrance valence on perception of facial  
89 attractiveness, as well as youthfulness and self-esteem, has been demonstrated across a  
90 number of studies [3,8,11,17,18]. There is evidence to suggest that the positive effect of  
91 pleasant fragrances on facial attractiveness follows a linear pattern, whereby increasing  
92 positive fragrance valence results in increased perceived attractiveness [3,11,17]. Moreover,  
93 higher-order associations with specific fragrances, such as gender effects, may modulate the  
94 impact of pleasant fragrance on perceived facial attractiveness. For instance, Risso et al.  
95 [19] observed that a pleasant caramel fragrance, associated with femininity, enhanced  
96 attractiveness of female faces, whilst a 'masculine' liquorice fragrance enhanced  
97 attractiveness of male faces. This finding suggests gender-congruence of an odour  
98 modulates cross modal influences on person perception [19]. In terms of mechanisms, the  
99 enhancement of facial attractiveness caused by pleasant fragrances may be facilitated by  
100 the privileged access to affective brain networks by our sense of smell [3]. This is reflected  
101 by activation of reward-related cortical structures such as the medial orbitofrontal cortex in  
102 response to pleasant fragrance [10,20,21], regions involved in affective processing such as  
103 bilateral parahippocampal gyrus and amygdala [22], and integrative cortices such as the  
104 anterior cingulate cortex for pleasant and unpleasant fragrances [21]. Although a number of  
105 event-related potential (ERP) studies have shown that facial attractiveness can modulate N1  
106 [23,24], P2 [25,26], N2 [25,27] P300 [28,29], late positive complex (LPC; [30,31] and late  
107 positive potential LPP [27], to our knowledge, no studies have specifically examined ERPs to  
108 facial attractiveness during fragrance presentation.

109

110 Although the majority of the research has focused on the influence of fragrances on  
111 perception of other's faces, a recent review highlights a growing body of evidence  
112 suggesting that fragrance can also impact self-perception Spence [15]. Self-perceived  
113 physical attractiveness and self-confidence were enhanced in a sample of men when they  
114 had previously applied an active deodorant containing a pleasant fragrance and  
115 antimicrobial ingredients designed to reduce malodour, compared to a control body spray

116 with no active ingredients [32]. Women also rated the men in the active deodorant condition  
117 as more attractive in dynamic video clips, but not static images. This suggests that self-  
118 confidence may have translated into perceptible changes in the men's non-verbal behaviour  
119 which influenced observer judgements. Taken together, this research has important  
120 implications for social communication, and further exploration of the role of fragrance  
121 valence on self-perception is warranted. The majority of research has focused on opposite-  
122 sex attractiveness ratings, and there is little evidence to suggest how cross modal perception  
123 might influence women's perception of other women's attractiveness.

124

125 Despite growing interest in this topic, the neural mechanisms underpinning cross-modal  
126 visual/olfactory interactions, particularly the spatio-temporal characteristics of these cross-  
127 modal interactions, are not yet well understood [12]. A handful of studies have explored the  
128 temporal characteristics of visual/olfactory cross- modal interactions. For example, Cook et  
129 al. [11] observed amplitude modulation of late (> 600 ms) and ultra-late (> 900 ms) positive  
130 potential ERP components in response to faces with neutral facial expressions presented 3s  
131 after a valenced fragrance. In the pleasant fragrance condition, greater negative amplitude to  
132 faces was elicited in the LPP component, across right posterior- and temporal-parietal  
133 electrodes. Moreover, during ultra-late latency epochs, faces presented in a pleasant  
134 fragrance condition elicited greater positivity in left lateral frontal-temporal electrodes. The  
135 authors concluded that these findings provide evidence that cross-modal evaluations for  
136 fragrance-faces stimuli are represented in the LPP at late stages of processing.

137

138 A further study by Cook et al. [12] explored the influence of fragrance valence on  
139 perceptions of emotional faces, including happy and disgusted facial expressions.  
140 Fragrance-face interactions modulated amplitude at earlier stages of processing in both the  
141 N200 and N400 ERP components. Unlike clean air and unpleasant fragrances, which were  
142 differentially impacted by face valence, pleasant fragrances modulated ERPs similarly for  
143 both happy and disgusted faces. This may demonstrate a broad effect of positively-valenced

144 fragrances, irrespective of the emotion depicted in the face, however, there has been no  
145 investigations into whether this effect would cross over to evaluation of self-images. More  
146 recently, Syrjänen et al. [16] observed enhanced N170 ERPs to disgusted faces when in the  
147 presence of a pleasant fragrance, suggesting that fragrances can bias socioemotional  
148 perception during early visual processing. However, early ERP modulation has never been  
149 observed in own neutral faces during pleasant fragrance presentation. It is also unclear  
150 whether such effects would be applicable across evaluation domains. Whilst odour has been  
151 shown to modulate self-perceived attractiveness and self-confidence in previous work  
152 (e.g.[32]), other related evaluative dimensions such as femininity and glamorousness are  
153 less well studied in the context of pleasant odours, however both are subject to  
154 modification/enhancement with other cosmetics such as make-up (e.g.[33]), and thus may  
155 capture unique variance in participants' experience of viewing face images.

156

157 To our knowledge, the current study is the first of its kind to explore the neural mechanisms  
158 of olfactory-visual interactions on perception of facial attractiveness for images of the self, as  
159 well as perception of other people's faces. Therefore, the aim of the current study was to  
160 investigate the spatio-temporal brain dynamics underpinning cross-modal interaction  
161 between simultaneous presentation of a fragrance and face image. Furthermore, we aimed  
162 to determine whether a pleasant fragrance, a commercially available body wash, would have  
163 a positive impact on subjective ratings of facial attractiveness of self and other images in the  
164 form of attractiveness, confidence, glamorousness and femininity. Given the paucity of  
165 research investigating cross modal influence of fragrance on same-sex attractiveness  
166 ratings, we were particularly interested in women rating other women. Based on prior  
167 literature, it was hypothesised that cross-modal face/fragrance effects for self and other  
168 faces in the presence of the pleasant fragrance would modulate mid and late latency ERP  
169 components involved in affective processing and cognitive evaluation during face  
170 perception.

171

## 172 **2.1 Methods**

173 The present study explored how a pleasant fragrance, compared to clean air, affects the  
174 electrophysiological activity of the cortex, measured using electroencephalography (EEG),  
175 during observation of self- or other-face images. The study was conducted in the EEG Brain  
176 and Behaviour laboratories of the University of Liverpool. EEG activity was recorded using a  
177 128-channel Geodesics (EGI, Oregon, USA) system designed for research purposes only.

178

### 179 **2.1.1 Participants**

180 22 healthy female participants aged 19 – 30 years (mean  $\pm$  standard deviation: 25.86  $\pm$  2.80)  
181 took part in the current experiment once written informed consent was given in accordance  
182 with the Declaration of Helsinki. The study was approved by the University of Liverpool  
183 Health and Life Sciences Research Ethics Committee (Psychology, Health and Society -  
184 5688). All participants were free from neurological or olfactory disorders. Data from 3  
185 participants were excluded from behavioural analysis, as they were identified as significant  
186 outliers on self-report ratings of visual stimuli ( $>\pm 3$  SD from mean), with a response pattern  
187 indicative of systematic responding. Data from 1 participant was excluded from EEG  
188 analysis due to excessive movement related artefacts in the EEG data. Hence, behavioural  
189 data from 19 participants, and EEG data from 21 participants were retained in the final  
190 analysis.

191

192 Females aged 18 – 30 years were eligible for inclusion. All participants were initially  
193 screened prior to beginning the experiment using a validated procedure known as the  
194 'Sniffin' Sticks' test (Burghart Messtechnik GmbH, Holm, Germany; [34]). The test involved  
195 presenting 12 fragrance pens approximately 3 cm beneath a participant's nostrils.  
196 Participants were asked to identify each of the 12 test fragrances from a selection of 4 labels  
197 for each. Nine correct detections (out of 12 probes) were required to confirm normal sense of

198 smell. All participants identified 9+ fragrances correctly and none were excluded from  
199 participation based on the 'Sniffin' Sticks' test outcome. Participants who self-reported  
200 neurological disorders such as epilepsy, olfactory disorders such as hyposmia or anosmia,  
201 or breathing disorders such as asthma were also excluded. Due to potential interference with  
202 electrodes, and to match the make-up free face stimuli selected from the database,  
203 participants were asked to avoid wearing makeup on the day when they attended to be  
204 photographed. They were also instructed not to smoke, eat, drink or chew gum 2 hours prior  
205 to the experiment, to avoid washing their hair the night before, or on the day of testing, and  
206 to avoid use of fragranced products such as perfume or deodorant on the day. Participants  
207 were reimbursed £30 for their time and travel expenses.

208

### 209 **2.2.1 Design**

210 The current study employed a within-subjects design to observe differences in behavioural  
211 and electrophysiological measures in two fragrance conditions (pleasant fragrance VS clean  
212 air) whilst viewing faces (self or other) displaying neutral emotional expressions and rating  
213 their attractiveness, femininity, glamorousness and confidence using visual analogue  
214 scales.

215

### 216 **2.3.1 Visual and olfactory stimuli**

217 In this experiment 12 face images of female actors, including a mixture of races and  
218 ethnicities, were obtained from the Chicago Face Database Set of Facial Expressions [35].  
219 All actors wore grey t-shirts and their faces displayed neutral expressions, with their head  
220 and shoulders squared to the camera. All images were in colour, sized at 1086 x 724 pixels  
221 with luminance and contrast standardised and a white background. These images will be  
222 henceforth referred to as 'other-images'. Images were selected to be representative of the  
223 participant sample. While participant ethnicity was not measured or reported in the present

224 study, we anticipated a diverse sample, and database images were selected in line with this.  
225 Database image and study participants were matched for age based on study inclusion  
226 criteria (age 18 – 30). As photographs of participants were taken on the day of the  
227 experiment and immediately loaded on to the experimental task, it was not possible to match  
228 images on dimensions of attractiveness, femininity, confidence and glamorousness.

229

230 For the self-photographs, 6 photographs of participants own faces were obtained,  
231 Participants were made aware in the participant information sheet that their faces would be  
232 photographed as part of the experiment. Participants had their photograph taken using a  
233 Nikon D3500 camera with a plain white background with studio grade LED lighting. In order  
234 to match other-images, they wore a plain grey t-shirt over their clothes with their shoulders  
235 squared to the camera and neutral facial expressions. Six photographs of each participant  
236 were taken by a researcher with participants' heads facing six different pre-marked angles  
237 (head turned approximately 90°, 45° and 22.5° to the left, and then 22.5°, 45° and 90° to the  
238 right) to create six 'self-image' stimuli. The decision to include 6 angles in the 'self' condition  
239 aimed to reduce repetition suppression which can negatively impact neural ERP responses  
240 [4].

241 Self-image selection was chosen by the experimenters; participants were not shown their  
242 photographs prior to completion of the experimental task, or offered opportunity to select  
243 their preferred images. Images were re-sized to 1086 x 724 pixels and matched for  
244 brightness to the other-images using Corel Photo Paint 2019. These will henceforth be  
245 referred to as 'self-images'.

246

247 Fragrance or clean air was administered through two tubes sitting approximately 2  
248 centimetres away from the nostrils, using a custom-built, computer-controlled 8-channel  
249 olfactometer (Dancer Design Ltd., UK). Fragrance pulses were embedded within a constant  
250 flow of clean air, to avoid a sudden pulse of air flow when the fragrance was delivered [36].  
251 Airflow was kept constant at 2.25 l/min in line with previous studies [12,14,37].

252

253 The experiment had two fragrance conditions; either ‘fragrance present’ or ‘clean air’ control.  
254 The pleasant fragrance stimulus was the commercially available LUX Magical Orchid body  
255 wash. This is a floral fragrance typically marketed at women and, as such, was selected as  
256 gender congruent and appropriate for addressing our study aims of exploring women’s  
257 perceived attractiveness of both themselves and other women. The body wash was  
258 presented undiluted via the olfactometer, which results in a perception that is highly similar  
259 to smelling the product from the bottle. The odourless inert compound, propylene Glycol  
260 (1,2-Propanediol 99%, Sigma-Aldrich Ltd., UK) was used for the clean air control and  
261 constant flow in interstimulus intervals. The olfactory stimulation procedure was modelled on  
262 previous studies [12]. The body wash was supplied by Unilever. The images and triggering  
263 of fragrance valves were controlled using Psychopy 20201.1.0 [38]. In between experimental  
264 blocks, an extractor fan was used to filter the environmental air and reduce exposure to  
265 residual fragrance in the Faraday cage.

266

#### 267 **2.4.1 EEG recordings**

268 EEG was recorded continuously over the whole scalp using a 128-channel Geodesics EGI  
269 System (Electrical Geodesics, Inc., Eugene, Oregon, USA) with a sponge-based Geodesic  
270 Sensor Net. The scalp sensors were placed according to the anatomical landmarks of the  
271 head; the pre-auricular points, the nasion and the inion. Electrode-to-skin impedances were  
272 kept below 10 k $\Omega$  and at equal levels across all electrodes. The recording band-pass filter  
273 was 0.01–1000 Hz, and the sampling rate was 1000 Hz. Electrode Cz was used as the  
274 reference electrode.

275

#### 276 **2.5.1 Procedure**

277 Upon entering the Brain and Behaviour Laboratory at The University of Liverpool, informed  
278 consent was obtained, and participants were screened to ensure they did not have any

279 allergies, asthma, or olfactory issues. Participants then entered a professional style photo  
280 booth (Havox® HPB 200 Photo Booth) and had pictures taken featuring face, down to  
281 slightly below level of shoulders using a Nikon D3500 camera. Whilst one experimenter was  
282 editing the images and matching them for brightness and size to the 'other-image' stimuli,  
283 the participant took part in the olfactory screen using the Sniffin' Sticks test. Following  
284 successful completion of the olfactory screen, the EEG cap was applied. After application of  
285 the EEG cap, participants were led into in a dimly lit, sound attenuated room and sat facing a  
286 19-inch LCD monitor (60 Hz refresh rate) placed 0.7 m in front of them. Once EEG signal  
287 was checked, the olfactometer head piece was fitted, and task instructions were given to  
288 participants.

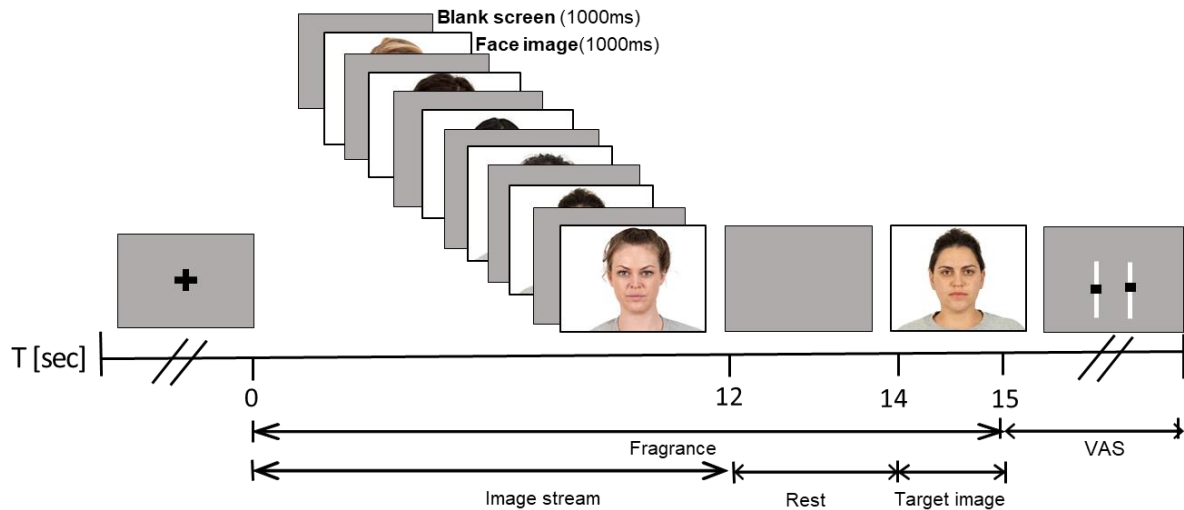

289

290 Before participants took part in the experimental task, baseline passive viewing EEG was  
291 measured (not reported) and a short task prior to the main experimental task was utilised to  
292 gain mean ratings of fragrance pleasantness and intensity for both the pleasant fragrance  
293 and the clean air. Participants were asked to rate the smell intensity from '0-not intense at  
294 all' to '100-very intense' and pleasantness from '0-neutral' to '100-extremely pleasant'.

295

296 The experimental task consisted of three blocks of 72 trials (216 trials in total). Each trial  
297 consisted of 6, 1 second, face presentations (2 "self-images" and 4 "other-images")  
298 displayed in a pseudorandomised, counterbalanced order, with a 1-second gap between  
299 each face presentation (i.e., each stream of images in a trial lasts 12 seconds; see Figure 1  
300 for a schematic illustration of a single trial). These 6 images shown in each stream were  
301 utilised for subsequent analysis of neural responses to self- and other – faces in each  
302 fragrance condition. The decision to nest multiple face images within a short fragrance  
303 exposure was taken to reduce impact of desensitisation which leads to reduced impact of  
304 fragrance stimuli on visual processing [39]. This stream of images was followed by a 2  
305 second gap, after which one of the faces from the stream was selected to be a target image  
306 and was presented again for 1 second. Immediately after presentation, participants were

307 prompted to rate this target image on two of a possible four rating scales; either  
 308 attractiveness, confidence, femininity or glamorousness, using on-screen visual analogue  
 309 scales. For example, participants rated attractiveness (from 0-extremely unattractive to 100-  
 310 extremely attractive) and confidence (0-extremely unconfident to 100-extremely confident).  
 311 During the exposure to the entire photo stream and final face presentation a 15 second  
 312 pulse of either the pleasant fragrance or clean air.  
 313

314  
 315 **Figure 1.** A flow chart depicting a single trial of the experiment. Each trial consisted of 6, 1 second, face  
 316 presentations, with a 1-second gap between each face presentation (i.e., each stream lasts 12  
 317 seconds). This was followed by a 2 second gap, after which one of the faces was presented again for  
 318 1 second and participants were prompted to rate this target image on two of a possible four  
 319 rating scales; either attractiveness, confidence, femininity or glamorousness, using on-screen visual analogue  
 320 scales.

321  
 322 At the start of each trial, participants viewed a black fixation cross on a grey background.  
 323 Participants were instructed to relax and breathe normally during this time. A pulse of  
 324 fragrance (pleasant fragrance or clean air) was triggered at the onset of a stream of six face  
 325 images (2 self-images, 4 other-images). After the sixth image, there was a 2 second rest, and  
 326 then one of the images from the stream was presented again for 1 second. Participants were  
 327 instructed to attend to the full image stream, but only rate the final image presented in each  
 328 stream, after the brief rest period. Immediately after image offset, two consecutive visual-

329 analogue scales prompted participants to rate the face in the target photograph on two of four  
330 measures (attractiveness, confidence, femininity and glamorousness), 15 seconds after  
331 fragrance onset. Utilising 2, out of 4 available, rating scales for each trial increased task  
332 engagement and prevented systematic responding. Once participants had completed these  
333 ratings, there was a 16 second washout period of clean air delivery before the next trial began.

334

335 In each block, trials were pseudorandomised so that each image (6 self-images, 12 other-  
336 images) were rated once per fragrance condition on each of the four self-report ratings. Both  
337 fragrances were presented in a pseudorandom order across each block; the same fragrance  
338 was presented no more than twice consecutively. In total, the full experimental session  
339 lasted approximately 90 minutes including experimental set up and the experimental task.

340

## 341 **2.6.1 Analysis**

### 342 **2.6.1.1 Behavioural analysis**

343 T-tests revealed intensity ratings were significantly higher for the fragrance condition ( $M=$   
344  $65.67$ ,  $SD = 15.60$ ) than a clean air control ( $M = 9.70$ ,  $SD = 11.73$ ),  $t(21) = 13.58$ ,  $p < .001$ ,  
345 Cohen's  $d = 0.29$ . Similarly, the fragrance condition ( $M = 52.56$ ,  $SD = 17.85$ ) was rated as  
346 significantly more pleasant than a clean air control ( $M = 6.20$ ,  $SD = 8.55$ ),  $t(21) = 12.38$ ,  $p <$   
347  $.001$ , Cohen's  $d = 0.24$

348

349 Significant outliers ( $n=3$ ) on self-report ratings of visual stimuli ( $>\pm 3$  SD from mean), were  
350 removed prior to analysis. As data following outlier removal was normally distributed,  
351 transformations were deemed unnecessary and not applied. This is in line with suggestions  
352 by Osborne [40] who cautions that transformations can complicate interpretation of data.  
353 Behavioural data was analysed using  $2 \times 2$  within-subjects ANOVA to observe whether there  
354 were statistically significant differences in evaluation of faces (self- or other-images) in the  
355 presence of different fragrances (pleasant fragrance or clean air). Four separate ANOVAs

356 were performed for each rating type; attractiveness, confidence, femininity and  
357 glamorousness. Significant main effects were investigated using pairwise comparisons using  
358 Bonferroni correction for multiple comparisons. Behavioural data was analysed using IBM  
359 SPSS Statistics for Windows, version 27 (IBM Corp., Armonk, N.Y., USA).

360

#### 361 **2.6.2.1 ERP analysis**

362 EEG recordings were pre-processed in BESA v. 6.1 software (MEGIS GmbH, Germany).  
363 Standard pre-processing procedures were implemented; data was down-sampled to 256 Hz,  
364 re-referenced to a common average using the common averaging method [41], and band-  
365 pass filtered (0.1 – 45 Hz). Eyeblinks were removed using principal component analysis and  
366 electrode channels containing large artefacts were interpolated. Trials contaminated by  
367 movement artefacts were identified through visual inspection and affected trials manually  
368 marked for exclusion from analysis. Stimulus onset was defined as the onset of each image  
369 present in the passive viewing stream, ERPs were time locked to the onset of each image in  
370 the stream. Trials were epoched -200 to 800 ms relative to image onset, and were baseline  
371 corrected -200 to 0 ms. This allowed us to analyse event related potentials (ERPs), which  
372 are averaged electrical brain responses gathered via EEG directly resulting from a particular  
373 event, which in this case, was the presence of an image of face.

374

375 After pre-processing, statistical analysis was performed in FieldTrip [42] (Donders Institute  
376 for Brain, Cognition and Behaviour, Radboud University, the Netherlands. See  
377 <http://fieldtriptoolbox.org>). To minimize the risk of false positive errors due to the large  
378 number of statistical tests, a hypothesis-independent permutation analysis (1000  
379 permutations), implemented in the statcond.m program in the EEGLab package [43] was  
380 used to perform a 2 x 2 ANOVA analysis at every electrode across every time point in each  
381 epoch (256 time points covering -200 ms to +800 ms relative to stimulus onset). This was  
382 used to identify clusters of electrodes demonstrating significant main effects of fragrance or

383 face image, or interactions between these conditions separately [44]. The cluster-based  
384 method provides a data-driven approach to assess effects of fragrance and face type on  
385 electrophysiological activity across all electrodes without making a priori assumptions  
386 regarding specific ERP components or scalp locations, while also controlling for multiple  
387 comparisons with no loss in statistical power.

388

389 In order to identify significant clusters and latencies in a more objective way, for each cluster  
390 in the solution, 95% confidence intervals for the mean IC cluster activity were calculated  
391 across the whole epoch; -200 to 800 ms. Only clusters in which the confidence intervals  
392 deviated from baseline (confirmed with one-way ANOVA analysis of grand average ERP  
393 data) were subjected to further statistical analysis. Data from electrode clusters and time  
394 periods which demonstrated effects in the multivariate analysis were exported for  
395 consideration of impact of the pleasant fragrance (versus clean air) on ERPs to self- and  
396 other-images. A statistical critical value threshold of  $p < 0.05$  was maintained throughout.

397

398 Correlational analyses were performed to understand the meaning of differential EEG effects  
399 for Self-Other conditions in clean, relative to the pleasant fragrance, conditions. Variables  
400 were computed by averaging self and other data across fragrance conditions and then  
401 subtracting the pleasant fragrance data from clean air. This method allowed exploration of  
402 whether greater change in brain activity correlated with greater change in behavioural  
403 ratings, and reduced the number of comparisons made. After removal of an outlier ( $> 3$  SDs  
404 outside of the mean voltage in the ERP components), a series of Spearman's rho  
405 correlations were performed for each variable of interest.

406

407 Finally, correlational analyses were also performed to investigate whether individual ratings  
408 of perceived fragrance pleasantness and intensity related to significant behavioural or EEG  
409 outcomes. Differential values for each behavioural or electrophysiological measure, which  
410 corresponded to significant results in ANOVA analyses, were correlated with individual

411 ratings of odour pleasantness and intensity. For example, the main effect of odour presence  
412 on attractiveness was calculated by summing attractiveness ratings for self- and other-  
413 images in the pleasant odour condition, and subtracting the sum of ratings for same  
414 conditions in presence of clean air. This value was correlated with individual ratings of  
415 perceived odour pleasantness and intensity.

416

## 417 **3.1 Results**

### 418 **3.1.1 Face ratings during fragrance presentation**

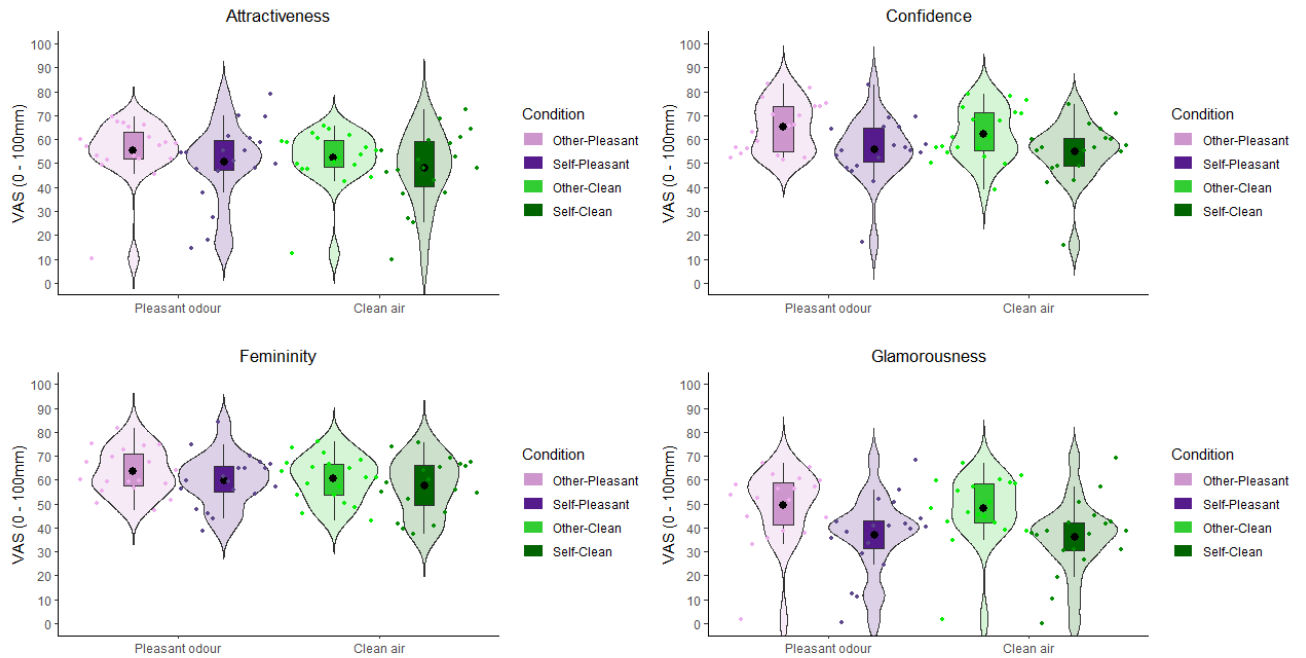

419 Figure 2 shows line graphs of the mean subjective ratings of attractiveness, confidence,  
420 glamorousness and femininity for self- and other-images when participants smelled the  
421 pleasant fragrance or clean air.

422

423 To examine the statistical significance, a series of 2 × 2 repeated measures analysis  
424 ANOVAs were conducted individually for attractiveness, confidence, femininity and  
425 glamorousness to consider the main effect of fragrance on each rating type, whether the  
426 evaluation of self-versus other-images differed, and whether there was any interaction effect  
427 between fragrance and face type (see 1).

428

429

430

431 **Figure 2.** Violin plots depicting distributions of subjective responses for ratings of attractiveness,  
 432 confidence, femininity and glamorousness in pleasant odour conditions for self (dark purple) and other  
 433 (light purple) images, and clean air condition with self (dark green) and other (light green) images. The  
 434 coloured individual dots show data points from each participant, the bold black dot indicates the  
 435 mean. The boxplots indicate the interquartile range (IQR) between the 25th and 75th percentile, and  
 436 the whiskers represent 1.5 times IQR.

437

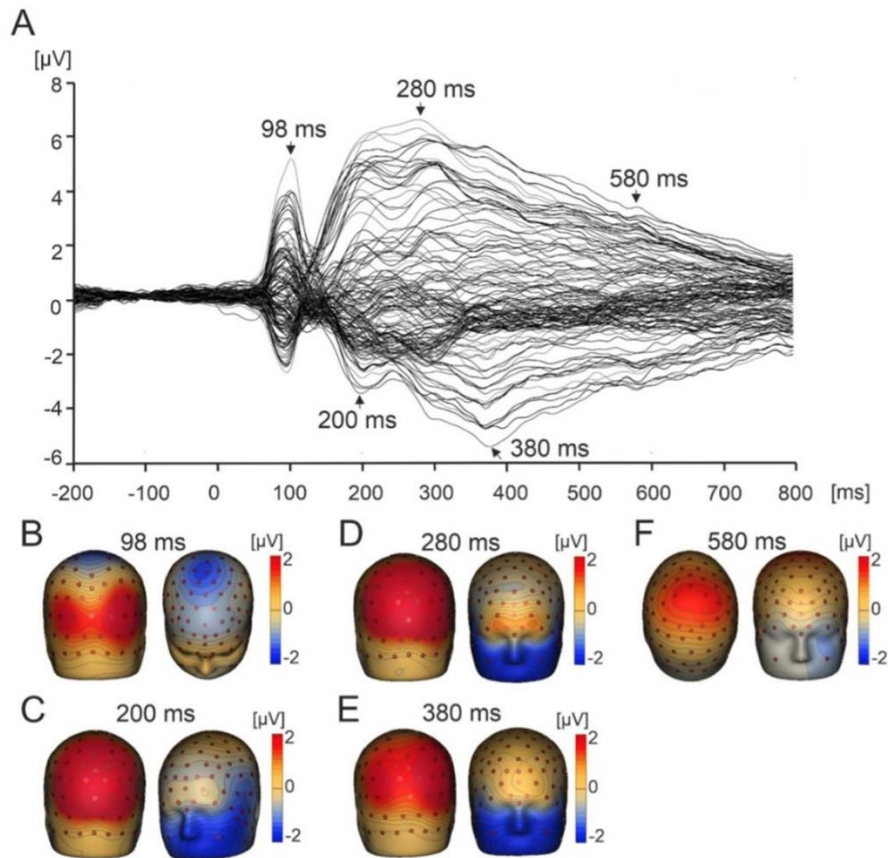

438 The ANOVAs revealed a significant main effect of fragrance across three of the four rating  
 439 scales ( $p < 0.05$ ) indicating more positive ratings for faces in presence of the pleasant  
 440 fragrance compared to clean air. This was identified in attractiveness ( $F(1, 18) = 5.204, p =$   
 441  $.035, \eta^2 = .22$ ) confidence ( $F(1, 18) = 6.223, p = 0.022, \eta^2 = .25$ ) and femininity ratings  
 442 ( $F(1, 18) = 4.479, p = .049, \eta^2 = .20$ ). There was no effect of fragrance on glamorousness  
 443 ratings ( $p > 0.05$ ) (See Figure 1). There was a main effect of 'self-other' for ratings of  
 444 confidence  $F(1, 18) = 4.881, p = .04, \eta^2 = .21$ ) and glamorous  $F(1, 18) = 15.092, p =$   
 445  $0.001, \eta^2 = .46$ ). This indicates that participants rated other-images significantly higher than  
 446 themselves on these rating scales. A similar non-significant trend ( $p < .1$ ) was evident in  
 447 attractiveness and femininity ratings, i.e., participants consistently rate themselves more  
 448 negatively than others. However, there were no significant interactions between fragrance  
 449 and self-other effects. This indicates that any perceived effect of fragrance is consistent  
 450 across self- and other-image ratings.

451

### 452 **3.2.1 ERP components**

453 Figure 3 demonstrates ERP components elicited in response to all faces across all trials and  
454 participants, regardless of fragrance condition, in the form of a grand average butterfly plot.

455 The grand average butterfly plot represents an overlay of ERP waveforms from every  
456 electrode, collapsed across all 4 conditions. This data was visually inspected to identify  
457 distinct components which correspond to peaks in global field power. Peak times  
458 representing maximal voltage in each recognisable distinct component were extracted via  
459 manual inspection. ERPs are characterized by their topography (i.e., where the activation  
460 occurs on the scalp) and their latency (i.e., when the effect occurs), which guide the  
461 interpretation of results. The first ERP component peaked at 98 ms, which is within the  
462 latency of the N1 Visual Evoked Potential (VEP) component; a component that peaks over  
463 central regions around 100 ms post-stimulus and is related to early visual processing of  
464 stimuli. A second negative ERP can be observed peaking at 200 ms post stimulus, which  
465 could be the N170, a component that is widely elicited in response to processing facial  
466 stimuli [45]. The next component showed a smaller negative peak at 280 ms which could  
467 also reflect the N2 component associated with early visual attention and evaluation [46].  
468 Another peak is present at 380 ms, the P300 component, which is involved in conscious  
469 attention to self-relevant stimuli [47]. Finally, a peak at 580 ms falls in the period of the LPP,  
470 a component related to higher-level processing of emotions

471

472 **Figure 3.** Butterfly plot of grand average waveforms to faces and corresponding scalp topographies  
 473 for peak latencies. (A) Butterfly plot representing data for all electrodes across the whole period of the  
 474 ERP averaged across all faces and fragrance conditions . Peak latencies of distinct ERP components  
 475 (N1, N2, P3, LPP) are highlighted with arrows (98 ms, 200 ms, 280 ms, 380 ms and 580 ms). (B)  
 476 Latency component 98 ms (N1). (C) Latency component 200 ms (N170). (D) Latency component 280  
 477 ms (N2). (E) Latency component 380 ms (P3). (F) Latency component 580 ms (LPP).  
 478

### 479 3.3.1 Effect of fragrances on ERPs

480 A permutation analysis was used to perform a  $2 \times 2$  ANOVA analysis at every electrode  
 481 across every time point in each epoch (256 time points covering -200 ms to +800 ms relative  
 482 to stimulus onset) to assess whether fragrance altered the neurophysiological processing of  
 483 faces reflected in cortical ERP clusters. The ANOVA revealed four scalp-time clusters that  
 484 showed significant effects of fragrance within the N1, N2, LPP and P3 components. Significant  
 485 main effects of fragrance at the N1 (fig 4), N2 (fig 5) and LPP (fig 6), and fragrance – image type  
 486 interactions at the N2 (fig 7) and P3 (fig 8) components are discussed in detail in the following  
 487 sections. Amplitude data was extracted from each of the scalp-time clusters and further one-

488 way ANOVAs were computed on the data using SPSS statistics (IBM Corp., Armonk, N.Y.,  
489 USA).

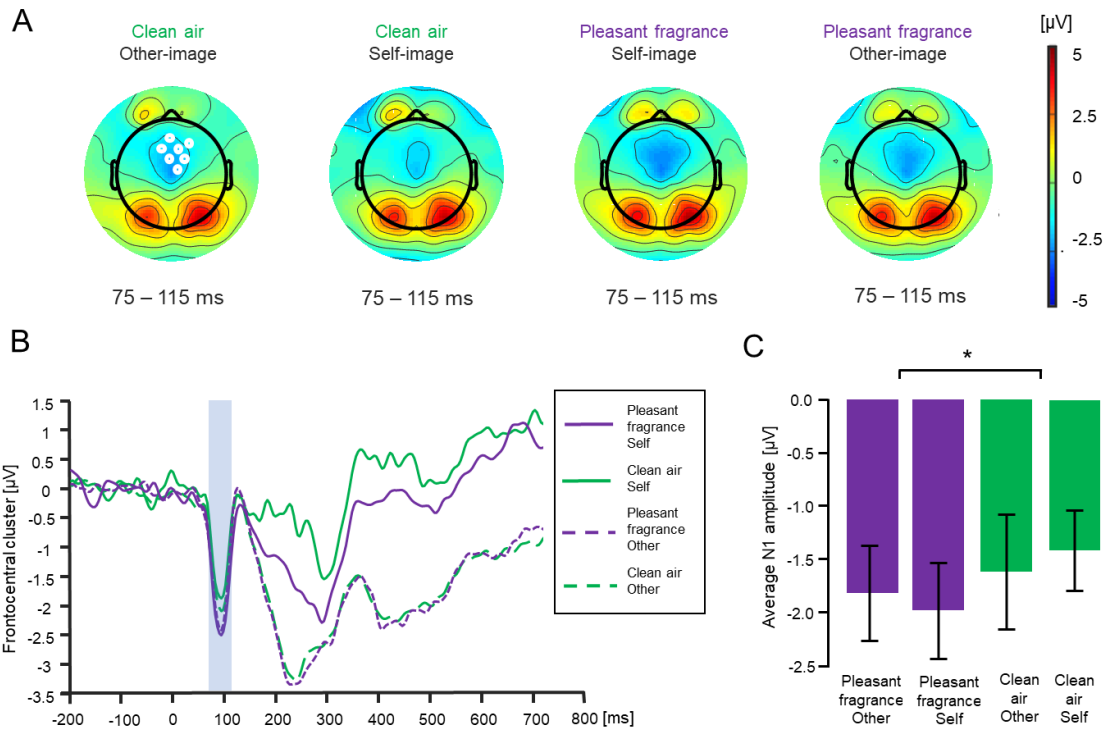

#### 490 **3.3.1.1 N1**

491 Figure 4 shows the first significant time cluster covering the time period 75-115 ms, which  
492 illustrates a main effect of fragrance type (pleasant fragrance versus clean air) on the ERP  
493 responses to faces. This falls within the latency of the N1 ERP component, which typically  
494 peaks around 100 ms with frontal negativity and occipital positivity. The corresponding  
495 topographic maps from each fragrance condition for each significant cluster (figure 4A) are  
496 shown with grand averaged waveforms ERPs across all participants highlighting the  
497 significant latency interval around the peak, and bar graphs showing the mean EEG scalp-  
498 amplitude ( $\mu\text{V}$ ) for each fragrance and face condition (Figure 4C).

499

500 A 2 (self- vs other-images)  $\times$  2 (fragrance: pleasant fragrance vs clean air) repeated measures  
501 ANOVA revealed a statistically significant main effect of fragrance ( $F(1, 20) = 10.799, p = .004,$   
502  $\eta^2 = .35$ ). This indicates that the negative N1 ERP brain component in a cluster of 7 central-  
503 frontal electrodes was enhanced during processing of faces in the presence of the pleasant  
504 fragrance compared to clean air conditions.

505

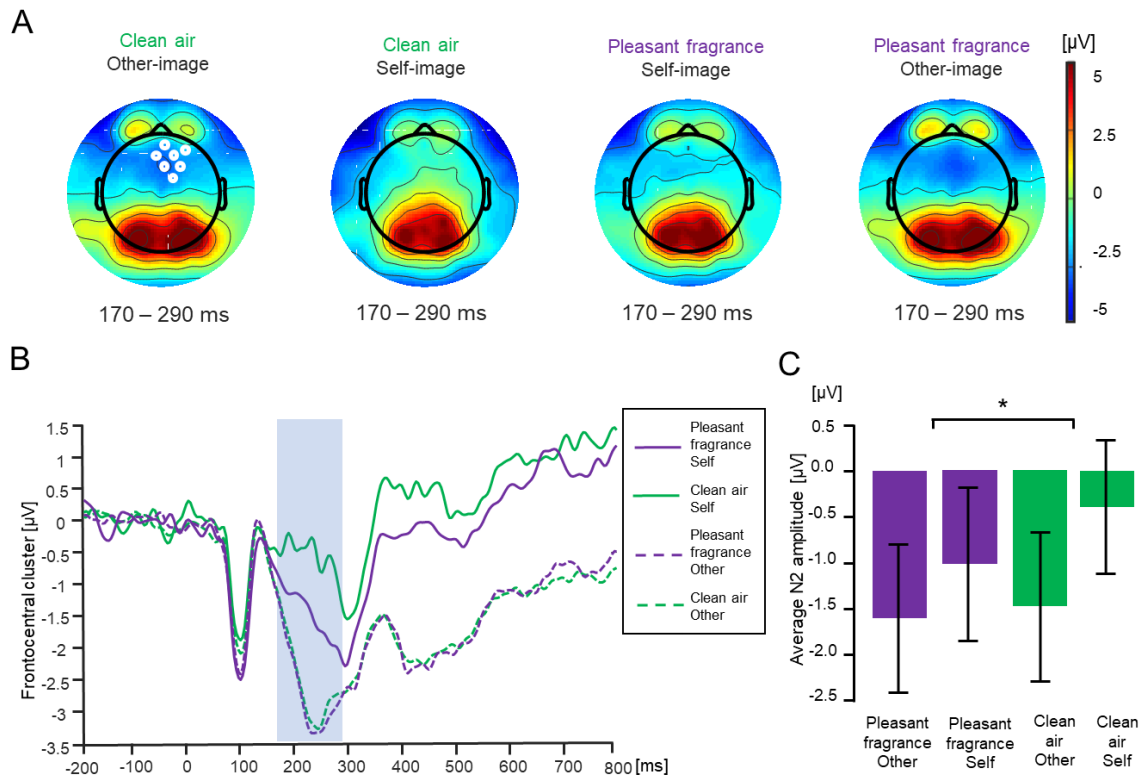

506

507 **Figure 4.** Impact of the pleasant fragrance on Facial ERPs at – N1 Component. (A) Whole head  
 508 topographies maps for grand averaged N1 (75 – 115ms) with differences in negative activation within  
 509 a middle frontal cluster of electrodes (E4, E6, E11, E12, E112 and E118 electrodes) when viewing  
 510 facial images (self- and other-images) in the presence of the pleasant fragrance versus clean air. B)  
 511 Grand Average ERP across a middle frontal cluster of electrodes between 75-115 ms. C) Bar chart of  
 512 the mean N1 amplitudes of ERP waveform depicted above over epoch 75 – 115 ms from the same  
 513 cluster of electrodes. The error bars shows the standard error.

514

515 **3.3.2.1 N2**

516 Figure 5 shows the second significant time cluster covering the time period 170 – 290 ms which  
 517 also illustrates a main effect of fragrance type (pleasant fragrance versus clean air) on the  
 518 ERP responses to faces. The ERP falls within the latency of the N2 ERP component, N2 is a  
 519 negative peak 200 – 300 ms post-stimulus over anterior central regions. The corresponding  
 520 topographic maps from each fragrance condition for each significant cluster (figure 5A) are  
 521 shown with grand averaged waveforms ERPs across all participants highlighting the significant  
 522 latency interval around the peak, and bar graphs showing the mean EEG scalp-amplitude (µV)  
 523 for each fragrance and face condition (Figure5C).

524

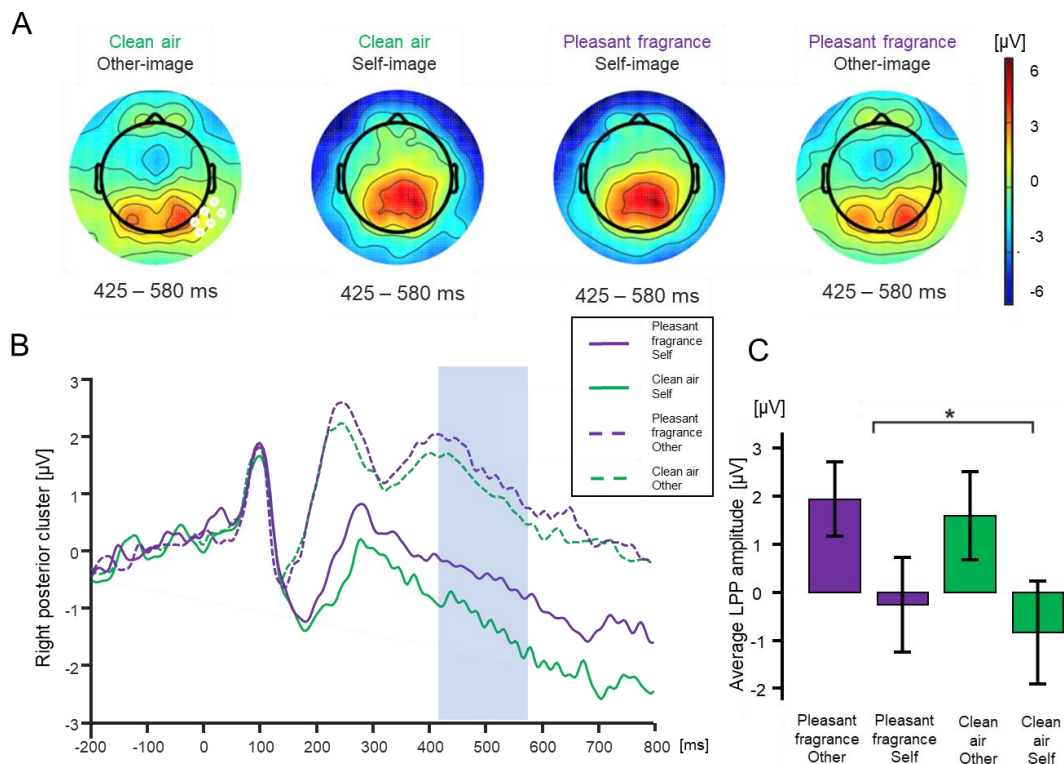

525 **Figure 5.** Impact of pleasant fragrance on Facial ERPs – N2 Component. (A) Whole head topographic  
 526 maps for grand averaged N2 (170 – 290ms) with differences in negative activation within a frontal-  
 527 central cluster of electrodes (E4, E5, E6, E11, E12, E112, E118) when viewing facial images (self- and  
 528 other-images) in the presence of pleasant fragrance versus clean air. (B) Grand average ERP waveform  
 529 within a frontal-central cluster of electrodes across all subjects comparing other-images in the presence  
 530 of pleasant fragrance (solid purple line) or a clean air control (solid green line) and self-images in the  
 531 presence of pleasant fragrance (dashed purple line) or clean air (dashed green line). Epoch of interest  
 532 170 – 290 ms post feedback-onset highlighted in grey (C) Bar chart of mean N2 amplitude of ERPs  
 533 over epoch 170 – 290ms from a cluster of fronto-central electrodes. The error bars show the standard  
 534 error.  
 535

536 A 2 (self- vs other-images) X 2 (fragrance: pleasant fragrance vs clean air) repeated measures  
 537 ANOVA revealed a statistically significant main effect of fragrance  $F(1, 20) = 10.165, p = .005,$   
 538  $\eta_p^2 = .34$  (See Figure 5), in a cluster of 7 central-frontal electrodes which demonstrated  
 539 enhanced N2 ERP negativity during processing of faces in the pleasant fragrance, relative to  
 540 clean air, condition.

541

542 **3.3.3.1 LPP**

543 Figure 6 shows the third significant time cluster covering the time period 425–580 ms which  
 544 also illustrates a main effect of fragrance type (pleasant fragrance versus clean air) on the  
 545 ERP responses to faces. The ERP falls within the latency of the LPP ERP component, which  
 546 is a positive waveform occurring in occipital/parietal electrodes, typically beginning around 400  
 547 ms. The corresponding topographic maps from each fragrance condition for each significant  
 548 cluster show positive activation in a right parietal cluster (Figure 6A) and are shown with grand  
 549 averaged waveforms ERPs across all participants highlighting the significant latency interval  
 550 around the peak, and bar graphs showing the mean EEG scalp-amplitude ( $\mu\text{V}$ ) for each  
 551 fragrance and face condition (Figure 6C).

552

553 **Figure 6.** Impact of the pleasant fragrance on Facial ERPs – LPP Component. (A) Whole head  
 554 topographic maps for grand averaged LPP (425 – 580 ms) displaying differences in positive activation  
 555 within a cluster of right posterior electrodes (E95, E96, E100, E101, E107, E108). (B) Grand Average  
 556 ERP waveforms comparing other-images in the presence of pleasant fragrance (solid purple line) or a  
 557 clean air control (solid green line) and self-images in the presence of pleasant fragrance (dashed  
 558 purple line) or clean air (dashed green line) across the right posterior electrode cluster for all  
 559 participants between 425– 580 ms (highlighted in grey), (C) Bar chart of the mean electrical  
 560 amplitudes of ERPs depicted above over epoch 425 – 580 ms (N2) from the same cluster of  
 561 electrodes. Error bars show the standard error.

562

563 A 2 (self- vs other-images) × 2 (fragrance: pleasant fragrance vs clean air) repeated measures  
564 ANOVA revealed a statistically significant main effect of fragrance, with enhanced positivity  
565 during LPP ERP component in a cluster of 6 right occipital-parietal electrodes in the pleasant  
566 fragrance condition compared to clean air regardless of face type  $F(1, 20) = 11.534$ ,  
567  $p = .003$ ,  $\eta_p^2 = .37$  (See Figure 5C).

568

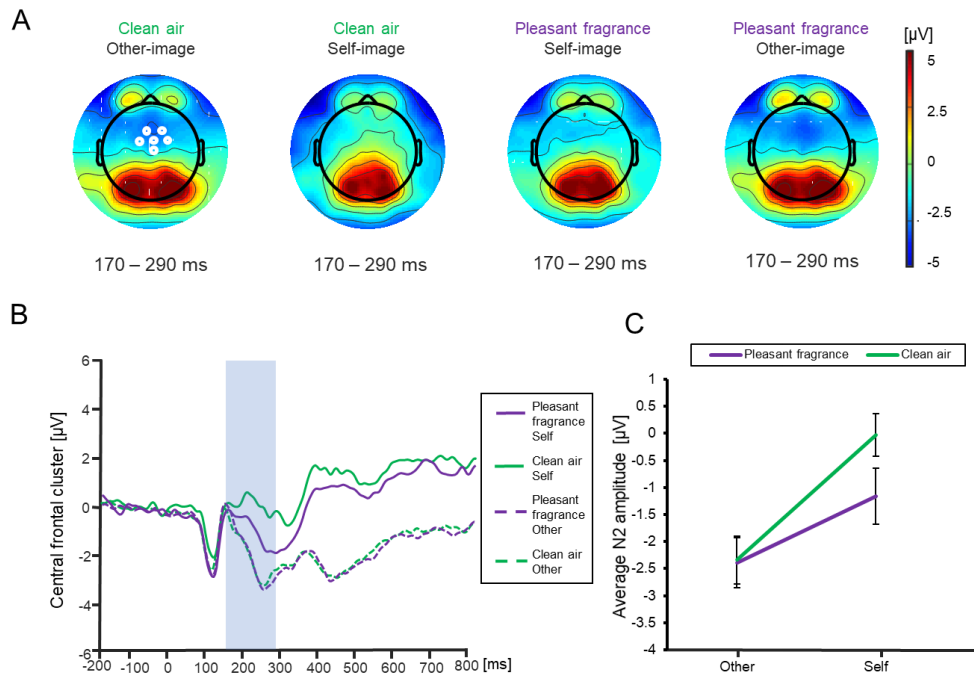

### 569 **3.4.1 Interactions between fragrance type and self-other image on ERPs**

#### 570 **3.4.1.1 N2**

571 In the second time cluster covering the time period 170-290 ms, in the latency of the N2  
572 component, an interaction between fragrance and face condition was observed. Figure 7A  
573 shows the topographic maps for each fragrance and face condition for a frontal negative  
574 cluster of electrodes (E4, E5, E6, E11, E12, E112, E118), demonstrating enhanced frontal  
575 negativity for other images regardless of fragrance condition. Figure 7B displays grand  
576 averaged N2 ERP waveforms across all participants highlighting the significant latency interval  
577 around the peak, with more negative N2 waveforms for other images regardless of fragrance  
578 condition.

579

580 A 2 (self- vs other-images) × 2 (fragrance: pleasant fragrance vs clean air) repeated measures  
581 ANOVA revealed a statistically significant interaction between fragrance and face-image in a  
582 cluster of 6 central electrodes, with self-images produced more negative N2 waveforms in the  
583 presence of the pleasant fragrance compared to clean air  $F(1, 20) = 15.623$ ,  $p = .001$ ,  $\eta_p^2 =$   
584  $.439$ . Figure 7C shows the interaction between fragrance type and face type, with other images  
585 producing more negative N2 amplitude regardless of fragrance type, however, the presence  
586 of the pleasant fragrance produced more negative N2 amplitudes in the self-image condition,  
587 compared to clean air.

588

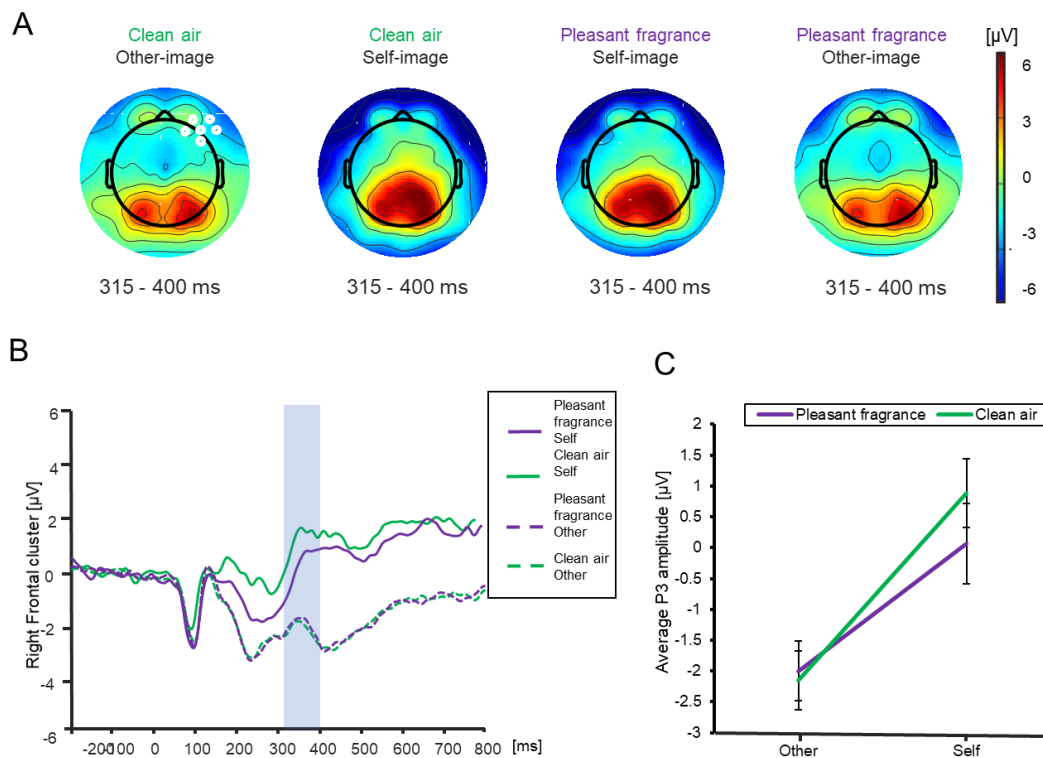

589 **Figure 7.** Interactions between fragrance and self-other effects – N2. (A) whole head topographic maps  
 590 displaying grand average activation between 170 – 290 ms for each fragrance and image condition type  
 591 in central frontal cluster of electrodes (E6, E7, E13, E106, E112, Cz). (B) Grand average N2 ERP  
 592 waveform displaying other-images in the presence of the pleasant fragrance (solid purple) or a clean  
 593 air control (solid green) and self-images in the presence of the pleasant fragrance (dashed purple) or  
 594 clean air (dashed green). Significant interval (170 – 290 ms) highlighted in grey. (C) Line graph of mean  
 595 N2 amplitude of ERPs between 170 – 290 ms in central frontal cluster of electrodes.  
 596

### 597 3.4.2.1 P3

598 Figure 8 highlights that an interaction effect was also observed in an additional time cluster  
 599 covering the time period 315 – 400 ms, in the latency of the P300 component. This cluster did  
 600 not initially show any main effect of fragrance on face processing within this time period in this  
 601 frontocentral cluster of electrodes. Figure 8A shows the topographic maps for each fragrance  
 602 and face condition for a frontal central of electrodes (E4, E5, E6, E11, E12, E112, E118),  
 603 demonstrating enhanced frontal positive activation for self-images, regardless of fragrance  
 604 condition. Figure 8B displays grand averaged P300 ERP waveforms across all participants  
 605 highlighting the significant latency interval around the peak, with more positive P300  
 606 waveforms for self faces regardless of fragrance condition.

607

608 The ANOVA revealed that the interaction between fragrance and self-other effects in the  
 609 central P3 (315 – 400 ms) was significant,  $F(1, 20) = 20.995$ ,  $p < .001$ ,  $\eta p^2 = .512$ , with the  
 610 pleasant fragrance significantly reducing the augmentation of P3 amplitude seen for self-  
 611 image viewing condition compared to other faces. Figure 8C Shows the interaction between  
 612 fragrance type and face type, with self-images producing enhanced P300 positive amplitude,  
 613 however the augmented P300 amplitude seen during self-images appears to be reduced in  
 614 the pleasant fragrance condition.

615

616 **Figure 8.** Interactions between fragrance and self-other effects – P3. (A) Whole head topographic maps  
 617 displaying differences in grand average P3 ERP activation between 315 – 400 ms in a fronto-central  
 618 electrode cluster. (B) Grand average ERP waveform across all subjects comparing P3 activity to own  
 619 face images in the presence of pleasant fragrance (solid purple line) or a clean air control (solid green  
 620 line) and other-face images in the presence of pleasant fragrance (dashed purple line) or clean air  
 621 (dashed green line). Epoch of interest 315 – 400 ms post feedback-onset highlighted in grey. (C) Line  
 622 graph displaying mean amplitude of ERPs over epoch 315 – 400 ms from frontocentral electrodes  
 623 cluster, showing reduced P3 amplitude for other-images across both fragrance conditions, and  
 624 enhanced P3 positivity for self-images, which was reduced when the pleasant fragrance was present).

625

626 **3.5.1 Correlations between behavioural ratings and ERP components**

627 Table 1 depicts the Spearman’s rho correlations between fragrance and image interactions  
 628 for the four behavioural ratings (attractiveness, confidence, femininity and glamorousness),  
 629 two face image conditions (own-face other-face), and each significant ERP component with  
 630 a main effect of fragrance (N1, N2, LPP) and two interaction effects (N2, P3).

631 Statistically significant positive correlations were found between attractiveness and femininity  
 632 ratings, femininity and confidence, N1 and N2 interaction, N2 and N2 interaction, P3a  
 633 interaction and attractiveness, P3 interaction and N2, and P3 interaction and N2.

634

635 **Table 1**

	1.	2.	3.	4.	5.	6.	7.	8.
<b>1. Attractiveness</b>	1.000	-	-	-	-	-	-	-
<b>2. Confidence</b>	.326	1.000	-	-	-	-	-	-
<b>3. Femininity</b>	.661*	.478*	1.000	-	-	-	-	-
<b>4.</b>	.404	-.026	-.018	1.000	-	-	-	-
<b>Glamorousness</b>								
<b>5. N1</b>	.225	-.199	.047	.348	1.000	-	-	-

636

637 Table 1 Correlations between fragrance-image interactions for four behavioural ratings  
638 (Attractiveness, Confidence, Femininity and Glamorousness) and five ERP components (N1,  
639 N2, LPP, N2 interaction and P3 interaction).

640 We also performed a series of Spearman's Rho correlations to compare individual differential  
641 ratings for each behavioural or electrophysiological measures that demonstrated significant  
642 results in ANOVA analyses, with subjective ratings of odour pleasantness and intensity. None  
643 of the behavioural or EEG outcomes demonstrated any significant relationship with individual  
644 ratings of odour pleasantness or intensity.

645

## 646 **4.1 Discussion**

647 Results showed that the pleasant fragrance of the commercially available body wash impacted  
648 how our participants rated faces of self and others. Self- and other-image faces were  
649 subjectively rated as more attractive, confident and feminine in the presence of the pleasant  
650 fragrance compared to an odourless control. Effects of the fragrance on electrophysiological  
651 processing of faces were evident in four well established ERP components covering early-to-  
652 late stages of visual processing; N1, N2, P3 and LPP. Moreover, there was evidence of a  
653 cross-modal fragrance-face interaction effect, with the pleasant fragrance particularly  
654 modulating ERPs to self-images in mid-latency N2 and P3 components.

655

### 656 **4.1.1 Effects of fragrance presence on face perception**

657 The current study findings revealed that when women's faces (self and other) were presented  
658 in conjunction with the pleasant fragrance of the commercially available body wash, the faces  
659 were rated as more attractive, confident and feminine than when the same faces were  
660 presented alongside an odourless control. This finding is consistent with previous literature  
661 [11] which observed that faces paired with a pleasant fragrance resulted in enhanced  
662 pleasantness ratings for both the face and the fragrance in a bidirectional manner. The current  
663 study revealed that self-images were rated less favourably overall compared to other images,  
664 however, the introduction of the pleasant fragrance was associated with reduced negativity of  
665 self-image ratings. The global enhancement that the pleasant fragrance had which positively  
666 impacted the ratings of faces (both self- and other-images) aligns with previous studies which  
667 observed global enhancements in pleasantness of other-face ratings irrespective of facial  
668 expression valence [12].

669

670 This study is the first to demonstrate the positive effect of a pleasant fragrance in a sample of  
671 women rating themselves and other women. The literature on multisensory fragrance/visual  
672 perception has shown differences in olfactory processing according to biological sex, with  
673 females typically demonstrating superior olfactory abilities [48], and male-female asymmetry  
674 in processing emotional olfactory stimulation [49,50]. Therefore, the current study is the first,  
675 to our knowledge, to demonstrate that a pleasantly valenced fragrance can not only amplify  
676 positive evaluation of attractiveness, femininity and confidence when viewing female faces of  
677 other, but can also amplify positive evaluation of these features in images of oneself.

#### 678 **4.2.1 Effects of fragrance-face combinations on electrophysiological responses.**

679 Effects of fragrance were observed during the N1 component of face ERPs. The N1 is an  
680 event related brain potential which shows a large negative deflection from baseline  
681 approximately 100 ms following the onset of a stimulus [51]. Research into N1 has shown  
682 evidence of multisensory integration and perception across fragrance and visual modalities,  
683 with fragrance modulating visual N1 and enhancing task performance by providing an  
684 olfactory association cue [52]. Furthermore, N1 has shown modulation according to  
685 emotional face expressions [53]. In the present study, the N1 ERP to face images was  
686 significantly enhanced in the presence of the pleasant fragrance, compared to clean air, in a  
687 cluster of centro-frontal electrodes, irrespective of whether participants were viewing own- or  
688 other-face images. This suggests that early stages of face-processing were enhanced in the  
689 presence of a pleasant fragrance, perhaps indicating that, in the context of a pleasant  
690 fragrance, faces receive greater attentional processing. This finding is supported by previous  
691 studies which have demonstrated ERP modulation by level of facial attractiveness at early  
692 stages of processing [54–57]

693

694 It is important to note that, as olfactory stimuli reach the nasal epithelium at a significantly  
695 slower rate than visual stimuli reach the retina [58], fragrance was continuously presented  
696 across each 15second trial, and was not time-locked to the specific target face being rated

697 for facial attractiveness. Consequently, global effects of the fragrance on mood and arousal  
698 would precede most images shown on a trial. Research indicates that valenced odours can  
699 induce a generalised mood state which could theoretically influence participants' experience  
700 and perception [59] Similarly, odours can induce general arousal, which can facilitate faster  
701 processing of affective stimuli such as faces [60]. It is plausible that the effects presented  
702 here could be explained by general enhancements of mood and arousal produced by the  
703 presence of a pleasant odour. Nonetheless, as fragrance presentation was altered on a trial  
704 by trial basis, this seems unlikely, and may be better explained by a cross-modal affective  
705 processes. Results are consistent with prior research suggesting greater early attentional  
706 processing, evidenced by enhanced N1 activity in response to faces presented in the context  
707 of anxiety related chemosensory signals [61]. However, to our knowledge, this is the first  
708 time N1 has been implicated in modulation of fragrance-face pairings by pleasant fragrance,  
709 extending these findings by demonstrating that a pleasant fragrance can also modulate N1  
710 amplitude in response to neutral faces. Combined with the fact that the presence of a  
711 pleasant fragrance was associated with enhanced ratings of facial attractiveness, confidence  
712 and femininity, this finding points towards a cross-modal influence of the pleasant fragrance  
713 in positively influencing evaluations of self- and other-image faces automatically and  
714 preconsciously.

715

716 Previous research has demonstrated that congruent cues from multiple modalities can  
717 facilitate object recognition speed and accuracy, particularly for fragrances and visual  
718 perception, as they have a natural correspondence [62,63]. This interesting finding in N1  
719 suggests that within 100 ms of viewing own- or other-face images, the presence of the  
720 pleasant fragrance of the commercially available body wash preconsciously and automatically  
721 upregulates the opinion of ourselves and others. What is striking is that this modulation of the  
722 N1 is not universal to all pleasant fragrances. A case in point is Cook et al. [12] who failed to  
723 find this extremely early modulation of the ERP by another pleasant fragrance (jasmine) in

724 participants viewing images of others from the same database. Whilst the present study only  
725 presented one pleasant and one neutral fragrance, it is not possible to determine whether the  
726 effects reported are specific to the pleasant fragrance used. Future research is required to  
727 elucidate the properties of fragrances that boost N1 to facial images, as compared to  
728 fragrances that do not.

729

730 In line with prior research [12], an effect of fragrances on face processing was also observed  
731 for the N2 component, which has been suggested to index enhanced facial attractiveness  
732 [25,27], and has been modulated by fragrance-face interactions [12]. In the current study,  
733 activation in the N2 component enhanced by the presence of the pleasant fragrance and the  
734 impact of fragrance was also greater for self-images, compared to others. Considering the  
735 self-report ratings, which were consistently less positive for self, compared to other-images,  
736 the interaction effect observed in N2 modulation, driven by the pleasant fragrance could index  
737 a reduction of negative attention to self. Therefore, following on from the automatic enhanced  
738 perception in the N1, the pleasant fragrance could continue to positively impact self-perception  
739 at an early, more conscious stage of processing. This finding is supported by studies  
740 examining ERPs to facial attractiveness which observed enhanced N2 amplitude to more  
741 attractive faces [25,27].

742

743 In line with our expectations, the multisensory effect of fragrance on face processing was also  
744 evident at later stages of processing within the LPP. The LPP is a positive deflection beginning  
745 around 400 ms post stimulus in the occipital parietal cortex and is typically associated with the  
746 processing of stimuli valence [64–67]. The LPP has also been implicated in the processing of  
747 facial attractiveness [27]. Specifically, the current study observed more positive LPP amplitude  
748 to both face-image types in the presence of the pleasant fragrance. Modulation of LPP  
749 amplitude according to face pleasantness [12] has been supported by prior research, and

750 studies have demonstrated that both negatively and positively valenced fragrances can  
751 modulate LPP amplitude and behavioural ratings during face processing [68].

752

753 Therefore, modulation of LPP to faces according to fragrance may reflect the complex aspects  
754 of evaluation of facial attractiveness, emotional content and stimuli valence which occurs in a  
755 top-down fashion, in contrast to bottom-up automatic cognitive processes which occur at  
756 earlier stages of processing, such as the N1. As the pleasant fragrance increased ratings of  
757 facial attractiveness, confidence and femininity in own and other-face images, this evaluation  
758 may reflect conscious appraisal of such features. Taken together, results suggest that the  
759 pleasant fragrance of the body wash alters top-down evaluation and engagement with face  
760 images and may amplify conscious positive appraisal of self and other faces. Therefore, the  
761 pleasant fragrance may upregulate women's perception of themselves and others, creating a  
762 globally more positive perception, reflected in enhanced LPP.

763

764 Finally, the current study observed an interaction effect between fragrance presence and face  
765 type within the P3 ERP component, a positive potential occurring between 250 – 450 ms in  
766 midline electrodes [69]. The P3 is known to be modulated by stimulus valence [69–73] facial  
767 attractiveness [28,29], and is an index of self-relevance [74]. The current study findings  
768 revealed enhanced positive activation of P3 for self-images compared to other-faces, but this  
769 difference was reduced in the presence of the pleasant body wash fragrance. Enhanced P3  
770 amplitude for own-face perception is in line with previous research which has shown enhanced  
771 P300 amplitude for own-face images compared to a famous face [31,75–79]. This is because  
772 the human brain performs in a specialised manner during processing one's own face,  
773 compared to others, and P3 is associated with processing of salient target stimuli [31]. It is  
774 possible that the presence of the pleasant fragrance amplified brain responses to own faces,  
775 reflected in the P300. However, the amplified P300 to self-faces was found to be reduced  
776 when in the presence of the pleasant fragrance, producing responses similar to the other-face  
777 condition. The current findings are also supported by the literature on ERP responses to

778 attractive faces, as previous studies have observed modulation of P3 amplitude to attractive  
779 faces [28,29] Consequently, the P3 (and earlier N2) interaction effects lead to the possibility  
780 that the pleasant fragrance impacts neurophysiological processing in a manner that reduces  
781 the negative salient impact of own-face viewing and which, therefore, allows women to see  
782 themselves through new eyes, with enhanced confidence, femininity and attractiveness.

783

784 An alternative explanation consistent with the finding that neural responses to self-images  
785 become more similar to images of other faces following odour pairing, is that self-images  
786 became more other-like due to association with an unfamiliar stimulus. According to Baron  
787 and Bronfen [80] exposure to an unfamiliar odour in the context of an artificial laboratory  
788 experiment is somewhat novel and may increase arousal. Given the artificial context of most  
789 visual-olfactory research, the influence of familiarity is difficult to determine, although future  
790 research may be warranted to address this possibility.

791

792 The current study has several limitations. The study could have benefitted from having more  
793 than one fragrance condition to compare against the baseline condition of clean air. While a  
794 growing body of evidence highlights the enhancement of perceived attractiveness by socially  
795 relevant chemosignals [81,82], there is limited evidence regarding the impact of non-social  
796 odours on evaluation of facial attractiveness. The inclusion of different positively valenced  
797 fragrances would have allowed us to further elucidate the specificity of our results in relation  
798 to the fragrance chosen and its impact on positive subjective ratings of faces and associated  
799 electrophysiological responses. Similarly, it would be useful for future research to include  
800 negatively valenced odour stimuli. At present it is not possible to conclude whether our  
801 results are specific to the qualities of the fragrance presented here.

802

803 It is unclear whether the reported effects are specific to perception of a person. In a recent  
804 review, Spence [15] highlights that, despite evidence that olfactory cues can bias evaluations  
805 of a variety of other stimuli, such as artwork, such effects may be more pronounced for face

806 perception given the biological relevance of odour for mate selection, which can serve as  
807 important socio-affective cues. Coupled with findings that affectively and semantically  
808 congruent stimuli are likely to be processed more efficiently [16], it is likely that such effects  
809 would be most pronounced for fragrances more strongly associated with human scents,  
810 such as body odour, perfumes and body washes. However, further exploration of  
811 crossmodal effects for incongruent odour-image pairings, and with a variety of non-human  
812 stimuli may warrant further exploration.

813

814 Additionally, participants rated the pleasantness and intensity of both the pleasant fragrance  
815 and clean air conditions, however, the pleasantness VAS scale was anchored from neutral to  
816 pleasant. The current study would have benefitted from anchoring the pleasantness scale from  
817 'unpleasant' to 'pleasant' in order to determine whether the scent was truly perceived as  
818 pleasant, however, on debriefing the participants, all of the participants confirmed that they  
819 found the fragrance to be pleasant. Moreover, the decision to include 6 images in the self-  
820 condition, was driven by pilot testing which revealed limited differentiation between images if  
821 more angles were included. The imbalance between self- and other- image types was deemed  
822 appropriate as self-other ERP comparisons were not a target for analysis. However, the  
823 imbalance of stimuli across conditions could feasibly impact on the interaction effects seen  
824 between odour and image type effects and future research should investigate the role of  
825 stimuli frequency.

826

827 In conclusion, the current study showed that the presentation of a pleasant fragrance from a  
828 commercially available body wash is associated with enhanced ratings of facial  
829 attractiveness, confidence and femininity of self-face and other-face images. These cross-  
830 modal effects of pleasant fragrance were also represented at both early (N1), mid-latency  
831 (P3 and N2) and later stages (LPP) of electrophysiological processing of both self- and  
832 other-face images. Finally, there was evidence pointing to positive impact of the pleasant  
833 fragrance for modulating ERP differences associated with viewing self- compared to other-

834 face images in mid-latency (N2 and P3) components. Taken together, these data indicate  
835 that the presence of the pleasant fragrance reduces critical processing of self-images and  
836 reduces the disparity between neurophysiological processing of self- and other faces that  
837 could clearly been seen when participants rated images in the presence of clean air. The  
838 enhanced evaluations of faces in the presence of the pleasant fragrance are reflected in  
839 augmented N1, N2, P3, and LPP components show similarities to neurophysiological  
840 evidence which highlighted these components for indexing of enhanced facial attractiveness.  
841 Notably, the current study was the first to observe N1 modulation in cross-modal fragrance-  
842 face interactions, which suggests that the studied pleasant fragrance can rapidly modulate  
843 N1 in response to neutral faces, impacting the earliest, bottom-up, stages of sensory  
844 processing. This important result shows the early impact of the pleasant fragrance on  
845 evaluation of faces at the subconscious level and the early latency of the N1 component  
846 suggests that the pleasant fragrance may positively impact early selective attention during  
847 the evaluation of faces. This finding, in combination with the behavioural ratings suggest  
848 pleasant fragrance can alter the processing of both own face and other people's faces at  
849 early stages of processing, and can alter evaluative judgments of attractiveness, confidence  
850 and femininity for both the self and others.

## 879 **Figure legends**

880 **Figure 1.** A flow chart depicting a single trial of the experiment. Each trial consisted of 6, 1  
881 second, face presentations, with a 1-second gap between each face presentation (i.e., each  
882 stream lasts 12 seconds). This was followed by a 2 second gap, after which one of the faces  
883 was presented again for 1 second and participants were prompted to rate this target image  
884 on two of a possible four rating scales presented sequentially; either attractiveness,  
885 confidence, femininity or glamorousness, using on-screen visual analogue scales.

886

887 **Figure 2.** Violin plots depicting distributions of subjective responses for ratings of  
888 attractiveness, confidence, femininity and glamorousness in pleasant odour conditions for  
889 self (dark purple) and other (light purple) images, and clean air condition with self (dark  
890 green) and other (light green) images. The coloured individual dots show data points from  
891 each participant, the bold black dot indicates the mean. The boxplots indicate the  
892 interquartile range (IQR) between the 25th and 75th percentile, and the whiskers represent  
893 1.5 times IQR.

894

895 **Figure 3.** Butterfly plot of grand average waveforms to faces and corresponding scalp  
896 topographies for peak latencies. (A) Butterfly plot representing data for all electrodes across  
897 the whole period of the ERP averaged across all faces and fragrance conditions . Peak  
898 latencies of distinct ERP components (N1, N2, P3, LPP) are highlighted with arrows (98 ms,  
899 200 ms, 280 ms, 380 ms and 580 ms). (B) Latency component 98 ms (N1). (C) Latency  
900 component 200 ms (N170). (D) Latency component 280 ms (N2). (E) Latency component  
901 380 ms (P3). (F) Latency component 580 ms (LPP).

936 **Figure 7.** Interactions between fragrance and self-other effects – N2. (A) whole head  
937 topographic maps displaying grand average activation between 170 – 290 ms for each  
938 fragrance and image condition type in central frontal cluster of electrodes (E6, E7, E13,  
939 E106, E112, Cz). (B) Grand average N2 ERP waveform displaying other-images in the  
940 presence of the pleasant fragrance (solid purple) or a clean air control (solid green) and self-  
941 images in the presence of the pleasant fragrance (dashed purple) or clean air (dashed  
942 green). Significant interval (170 – 290 ms) highlighted in grey. (C) Line graph of mean N2  
943 amplitude of ERPs between 170 – 290 ms in central frontal cluster of electrodes.

944

945 **Figure 8.** Interactions between fragrance and self-other effects – P3. (A) Whole head  
946 topographic maps displaying differences in grand average P3 ERP activation between 315 –  
947 400 ms in a fronto-central electrode cluster. (B) Grand average ERP waveform across all  
948 subjects comparing P3 activity to own face images in the presence of pleasant fragrance  
949 (solid purple line) or a clean air control (solid green line) and other-face images in the  
950 presence of pleasant fragrance (dashed purple line) or clean air (dashed green line). Epoch  
951 of interest 315 – 400 ms post feedback-onset highlighted in grey. (C) Line graph displaying  
952 mean amplitude of ERPs over epoch 315 – 400 ms from frontocentral electrodes cluster,  
953 showing reduced P3 amplitude for other-images across both fragrance conditions, and  
954 enhanced P3 positivity for self-images, which was reduced when the pleasant fragrance was  
955 present).
