ACKNOWLEDGEMENTS

Foremost, I would like to express my sincere gratitude to my advisor Prof. Jianliang Xiao for the continuous support of my Ph. D study and research, for his patience, motivation, enthusiasm, and immense knowledge. His guidance helped me in all the time of research and writing of this thesis. I could not have imagined having a better advisor and mentor for my Ph. D study.

My sincere thanks also go to my co-advisor Prof. Can Li from Dalian Institute of Chemical Physics (DICP), who has enlightened me the first glance of research. I am grateful for his support, encouragement, insightful discussions and advice. I truly feel privileged to be a member of his group.

Besides my advisors, I would like to particularly thank Dr. Shengmei Lu from DICP for her selfless help and for the stimulating discussions. In addition, her beautiful personality has influenced me in many ways. I would like to show my gratitude to Dr. Xin Zhou who worked in DICP previously for her kind help on computational studies. I also thank Dr. Chao Wang from Shaanxi Normal University for his help on thesis preparation.

It is hard to thank everyone who helped me and describe all the moments that touched me deeply in such a limited page, but still I would like to thank my fellow labmates in Xiao group: Dr. Xiaofeng Wu, Dr. Jianjun Wu, Dr. Jen Smith, Dr. Jonathan Barnard, Dr. Weijun Tang, Dr. Ho Yin Li, Dr. Angela Gonzalez de Castro, Dr. Dinesh Talwar, Edward Booth, Thomas White and Ziyu Wang, for the experimental help in lab, for the helpful discussions and suggestions, for the time we worked together and for all the fun we have had in the past years. Also I thank my labmates and friends in Can Li group: Dr. Jun Li, Dr. Yan Liu, Dr. Chunmei Ding, Dr. Rengui Li, Dr. Jijie Wang, Dr. Jingxiu Yang, Dr. Wengang Guo, Mingpan
Cheng, Bao Zhang, Ping Cheng, Bo Yuan, Ping Chen and Xianghui Liu.

Thanks to all the staff and technicians in the chemistry department of University of Liverpool and DICP, who have helped me a lot both at work and in personal life.

Last but not least, I would like to thank my family for their endless love and support, without which I wouldn’t have achieved anything. I am grateful to have Xinchun Mao as my best friend and partner who helped me enormously.
ABSTRACT

The concentration of CO$_2$ in the atmosphere continues to increase due to an escalating rate of fossil fuel combustion, causing ever mounting concern about climate change. Meanwhile CO$_2$ is an abundant, safe and renewable C1 source. Thus transformation of CO$_2$ to value-added chemicals is of great significance and has been extensively investigated in the past decades. Homogeneous hydrogenation of CO$_2$ to formic acid (FA) especially has drawn significant attention, not only because FA itself has various applications including FA fuel cell, but also because FA can be a good hydrogen storage medium. The hydrogenation of CO$_2$ using such as solar-generated H$_2$ to produce FA, which is readily transportable, and the dehydrogenation of FA to release H$_2$ provide a decent strategy for hydrogen storage via CO$_2$ recycling.

However, it remains a challenge for the efficient hydrogenation of CO$_2$ to FA and FA dehydrogenation under mild conditions, especially for the aqueous phase reaction. Bearing these in mind, this work focus on the development of homogeneous catalysts for this reversible transformation and the main results are summarized as follows:

1. Cyclometallated [IrCp*(N$^\text{C}$)Cl] complexes (N$^\text{C}$ = 2-aryl imidazoline ligand) have been synthesized as the catalyst for the homogeneous hydrogenation of CO$_2$ to formate, and satisfactory reactivity (TOF: 57330 h$^{-1}$, TON: 102200) was achieved at 80 °C in a mixture solution of MeOH/H$_2$O. Water has been found to play an important role in this reaction and the catalysts with hydrophilic ligands show much higher activity in the hydrogenation of CO$_2$ than those with hydrophobic ligands.
2. Considering the electronic property of the ligand and catalyst water solubility, water-soluble iridium complexes \([\text{IrCp}^*)(N,N')\text{Cl}]\text{Cl}\) bearing conjugated \(N,N'\)-diimine ligands were subsequently synthesized and applied to \(\text{CO}_2\) hydrogenation. This catalyst is capable of efficiently hydrogenating \(\text{CO}_2\) to produce FA directly in water without any additives under mild reaction conditions. At 80 °C, the reaction turnover frequency (TOF) exceeds 13000 h\(^{-1}\) at 5.0 MPa of \(\text{H}_2/\text{CO}_2\) (1:1).

3. FA dehydrogenation to \(\text{H}_2\) and \(\text{CO}_2\) is studied using the iridium catalyst \([\text{IrCp}^*)(N,N')\text{Cl}]\text{Cl}\) in water without any additives, affording a TOF of 487500 h\(^{-1}\) at 90 °C and a turnover number (TON) of 2400000 with \textit{in situ} prepared catalyst at 80 °C, the highest values reported for FA dehydrogenation to date.

4. In addition, the FA dehydrogenation is shown to be catalyzed by \([\text{RhCp}^*\text{Cl}_2]_2\) in the FA/NEt\(_3\) azeotrope and is found to be accelerated by the addition of simple halide ions, especially \(\text{I}^-\).

**Key words:** CO\(_2\) hydrogenation, formic acid, formic acid dehydrogenation, iridium catalysts, homogeneous catalysis

Chapter 1 Introduction - Recent Development in Homogeneous Hydrogenation of CO₂ to Formic Acid and Formic Acid Dehydrogenation
1.1 Current Research Status of CO$_2$ Chemistry

The global atmospheric CO$_2$ level has been increasing continuously since the industrial revolution in the 19$^{\text{th}}$ century due to the excessive consumption of fossil fuel (coal, petroleum, natural gas), which has disequilibrated the natural carbon cycle. The concentration of CO$_2$ in the atmosphere has reached unprecedented level of over 400 ppm recently (Scheme 1.1) from 280 ppm when it was before the year 1800,$^{[1]}$ causing ever increasing concern about climate change as CO$_2$ is one of the main green-house gases.

![Scheme 1.1 Atmosphere CO$_2$ concentration during the past 50 years. Copyright: Scripps Institution of Oceanography, UC San Diego.](image)

Currently, there are mainly two strategies to cut down CO$_2$ emissions: on the one hand, the CO$_2$ capture and storage (CCS) as well as the utilization of CO$_2$ as a renewable and environmentally friendly source of carbon can directly reduce the atmospheric CO$_2$ concentration,$^{[2-5]}$ on the other hand, improving the energy utilization efficiency and developing sustainable clean energy such as hydrogen can ultimately reduce the CO$_2$ emissions.$^{[6-8]}$ Both have become hot research topics and have been intensively studied. At present, the large-scale CO$_2$ capture technology is growing mature at the main energy and chemical industry points,$^{[9]}$ and
the subsequent processing of CO₂ for utilization has become the key step. CO₂ can be utilized physically and chemically. For the physical utilization, besides the CO₂ storage process, it can be used as an oil displacement agent and a green extraction solvent at its supercritical phase, and in food industry and agriculture. However, these processes only recycle the CO₂ instead of diminishing it, especially considering the tremendous CO₂ emission per year, and thus can’t fundamentally solve the CO₂ problems.

The chemical utilizations of CO₂ focus on the conversion of CO₂ to value-added chemicals and fuels that will not only reduce CO₂ emissions in areas where geologic storage may not be an optimal solution but also replace fossil source with CO₂ as an abundant, non-toxic, cheap, environmentally benign and renewable C1 resource, thus enabling CO₂ into the carbon cycle rather than an increasing waste.

![Scheme 1.2](image)

**Scheme 1.2** Transformations of utilizing CO₂ as alternatives to petrochemicals (Taken from ref. 10).

As shown in Scheme 1.2, the chemical utilization of CO₂ mainly includes two fashions distinguished by the oxidation state of carbon. Firstly, the CO₂ recycling approaches don’t involve the change of the central carbon’s oxidation state and no
related energy storage process occurs. Examples are the synthesis of urea, carbonates, and poly/cyclic-carbonates from CO_2.\textsuperscript{[14,11-14]} Secondly, the CO_2 reduction approaches refer to the stepwise hydrogenation of CO_2 to formic acid, formaldehyde, methanol, methane and their derivatives such as polyols, carboxylic acids, amides, esters and ethers.\textsuperscript{[15,16]} During the reduction process, the oxidation state of central carbon decreases, realizing energy storage. The CO_2 reduction not only offers a convenient synthesis strategy utilizing CO_2 as building block but also has great significance from the viewpoint of sustainable fuel production; thus it has gained more and more attention during the past decades.

CO_2 reduction is generally difficult because CO_2 possesses the highest oxidation state of carbon, and is thermodynamically stable and kinetically inert. The standard formation heat of CO_2 is -394.38 kJ/mol, and the C=O bond energy is 749 kJ/mol. Therefore the reactions that generate reduced forms of CO_2 always require energy input and oxygen acceptors,\textsuperscript{[16-22]} such as H_2, silane, borane and carbanion, etc. Because H_2 can be easily obtained from water nowadays and the corresponding reduction process gives varieties of valuable products without generating much waste, the CO_2 hydrogenation technology has become one of the core technologies of CO_2 reduction and has been widely studied.

\section*{1.2 Recent Development on Homogeneous Hydrogenation of CO_2 to Formic Acid/Formate}

Formic acid (FA) is the main product in homogeneous hydrogenation of CO_2. Only a few examples give CO, methanol and even methane as products; but the reactivity and selectivity are low.\textsuperscript{[23-25]} Hydrogenation of CO_2 to FA is endergonic in the gas phase (eqn. 1.1), but exergonic in the aqueous phase (eqn. 1.2); thus solvent affects this reaction greatly. For instance, this reaction has been investi-
gated in a wide variety of organic solvents, ionic liquids, water and supercritical CO$_2$. Moreover, most of the currently reported homogeneous catalytic systems need the addition of base to enhance the productivity because base can consume the generated FA and thus shift the equilibrium forward (eqn. 1.3).

\[
\text{CO}_2 (g) + \text{H}_2 (g) \rightleftharpoons \text{HCOOH} (l)
\]
\[\Delta G^\circ = 32.8 \text{ kJ/mol}\]  
\[\text{CO}_2 (aq) + \text{H}_2 (aq) \rightleftharpoons \text{HCOOH} (l)\]  
\[\Delta G^\circ = -4 \text{ kJ/mol}\]  
\[\text{CO}_2 (aq) + \text{H}_2 (aq) + \text{NH}_3 (aq) \rightleftharpoons \text{HCOO}^- (aq) + \text{NH}_4^+ (aq)\]
\[\Delta G^\circ = -35.4 \text{ kJ/mol}\]

The synthesis of FA/formate by the hydrogenation of CO$_2$ was first discovered by Farlow and Adkins in 1935 using Raney nickel as the catalyst.\cite{26} The first homogeneously catalyzed example was reported by Inoue et al. in 1976.\cite{27} Extensive studies have been done afterwards to develop catalysts based on Rh, Ru, Pd, Ir, Fe, Co complexes and so on, for the hydrogenation of CO$_2$ to FA. The catalytic metal center, along with the coordinating ligands which could regulate the electronic and steric structure of the metal center, determines the reactivity and selectivity of the hydrogenation of CO$_2$. Ligands shown to be active towards the hydrogenation of CO$_2$ include phosphine ligands, pincer type ligands (PNP, PCP, PNN, etc.), N-heterocyclic carbene ligands and N,N-chelated ligands (pyridine and pyrimidine derivatives). The resulting state-of-the-art homogeneous catalyst systems developed during the past decades have been adequately summarized in the literature.\cite{17} Several reports have stated that catalysts with electron donating ligand are beneficial for the hydrogenation of CO$_2$.\cite{28-30} But beyond that, there’s no rule to follow with respect to the influence of ligand structures on the

hydrogenation activity, with each type of the above mentioned ligands showing good examples of hydrogenation at certain reaction conditions.

For industrial production, which is the long-term goal of CO_2 hydrogenation research, mild reaction conditions, simple catalytic systems and green solvents are always desired. Thus this section will focus on the recent development on homogeneous hydrogenation of CO_2 to FA/formate, highlighting the most efficient catalytic systems under typical reaction conditions (Table 1.1), e.g. non-aqueous/aqueous systems and basic/base-free reaction systems.

### 1.2.1 Hydrogenation of CO_2 to formate in organic solvent

In most of the currently reported homogeneous catalyst systems, base is needed to enhance the hydrogenation of CO_2 to formate because: i) base consumes the generated FA and thus thermodynamically shifts the equilibrium forward; ii) base has been found to accelerate the H_2 heterolysis during the catalytic cycle, therefore kinetically promoting the catalytic activity.

The landmark work by Inoue et al. in 1976 using triphenylphosphine (PPh_3) complexes of Ru, Rh, Ir, etc., created the new research field of homogeneous hydrogenation of CO_2 to FA.\[^{27}\] The reaction was carried out using a mixture of 2.5 MPa CO_2 and 2.5 MPa H_2 in benzene containing a catalyst, a small amount of water and a base (amine) at room temperature, and a turnover frequency (TOF) of 4 h\(^{-1}\) and turnover number (TON) of 87 after 20 h were obtained.

In 2013, Linehan et al. reported a Co complex, Co(dmpe)_2H (dmpe: 1,2-bis(dimethylphosphino)-ethane, P1, Scheme 1.3), for the hydrogenation of CO_2 in THF.\[^{31}\] In the presence of a very strong base, Verkade’s base, at room temperature, the high TOFs of 3400 h\(^{-1}\) and 74000 h\(^{-1}\) were achieved under 0.1 MPa and 2.0 MPa of CO_2/H_2 (1:1), respectively. One drawback of this catalytic reaction is the requirement of Verkade’s base (pKa = 33.6) for regeneration of
Co(dmpe)$_2$H from [Co(dmpe)$_2$(H)$_2$]$^+$. 

Scheme 1.3 Examples of the phosphine and pincer ligands used for the hydrogenation of CO$_2$

Very recently, Pidko et al. developed a highly stable temperature-switchable Ru-based system for the reversible hydrogenation of CO$_2$ that exhibits unprecedented rates for H$_2$ loading and release under mild conditions.$^{[32]}$ Using DMF as a solvent, DBU as a base at 120 °C and 4.0 MPa H$_2$/CO$_2$ (3/1), the Ru-PNP complex [RuH(Cl)(CO)(P$_2$)] (P2, Scheme 1.3) provided a TOF as high as 1100000 h$^{-1}$, which represents one of the highest values reported to date. Based on the kinetic studies (Scheme 1.4), CO$_2$ insertion (a-H to a*-HCOO) is postulated to be the rate determining step (RDS), which implies that the strength of the base promoter does not influence the reaction rate but it has a substantial effect on the reaction thermodynamics.

Scheme 1.4 Proposed catalytic cycle for the hydrogenation of CO$_2$ with Ru-PNP catalyst (Based on ref. 32).
Moreover, other catalytic systems have also been reported for CO\textsubscript{2} hydrogenation to formate in organic solvents like DMSO, methanol, toluene, diglyme, and ethanol.\textsuperscript{[33-39]} 

1.2.2 Hydrogenation of CO\textsubscript{2} to FA/formate using scCO\textsubscript{2} as solvent

Supercritical CO\textsubscript{2} (scCO\textsubscript{2}) could act as both reactant and solvent, and leads to better mass transport and heat transfer properties as well as high solubility of H\textsubscript{2}.

In the 1990’s, Noyori and Jessop et al. carried out the hydrogenation of CO\textsubscript{2} in scCO\textsubscript{2} mainly using ruthenium phosphine complexes as catalyst, and the reaction needs additives such as amine and methanol.\textsuperscript{[40]} Later, Jessop et al. developed a remarkable catalytic system with [RuCl(OAc)(PMe\textsubscript{3})\textsubscript{4}] (TOF up to 95000 h\textsuperscript{-1}) in scCO\textsubscript{2}.\textsuperscript{[41]} The study also revealed an accelerating effect on the rate of the hydrogenation reaction by utilizing appropriate amine and alcohol adducts. While Lewis bases are required for formate generation by CO\textsubscript{2} hydrogenation, the role of alcohol is not well-known. Alcohols may not generate carbonic acids, but it could be involved as a proton donor and hydrogen-bond donor.\textsuperscript{[41, 42]}

In 2012, Leitner et al. proposed a new concept that applies continuous-flow hydrogenation of scCO\textsubscript{2} to produce pure formic acid in a single process unit as shown in Scheme 1.5.\textsuperscript{[43]} They first identified a suitable combination of catalysts and ionic liquid (IL) matrices in batch reactions using triethylamine (NEt\textsubscript{3}) as base and IL as the stationary phase, and achieved high initial TOF using a ruthenium catalyst [Ru(cod)(methallyl)\textsubscript{2}]/PBu\textsubscript{4}TPPMS (cod = 1,5-cyclooctadiene, TPPMS = monosulfonated triphenylphosphine). When using IL1 containing intrinsic anion basicity as the liquid phase, a TON of 1970 and a TOF of 295 h\textsuperscript{-1} were obtained in a continuous-flow system. FA extraction from the nonvolatile amine-functionalized IL was found to be the limiting factor under the continuous-flow conditions. Anyhow, free FA can be collected via the integrated product
separation, which is eventually required for most applications.

**Scheme 1.5** Process for the direct continuous-flow hydrogenation of CO₂ to free FA based on a two-phase system (Redraw from ref. 43).

### 1.2.3 Aqueous hydrogenation of CO₂ to formate

As a green solvent, water has been explored as solvent for various catalytic reactions. In particular, aqueous phase hydrogenation of CO₂ has been explored extensively, and sometimes the limitation is the solubility of catalyst in water.

In 1993, Leitner et al. first reported water-soluble rhodium-phosphine complexes that can catalyze the hydrogenation of CO₂ to formate in water/amine mixtures. Among the catalysts examined, RhCl(tppts)₃ (tppts: tris(3-sulfonatophenyl)phosphine) exhibited a high TON of 3440 at room temperature and 4.0 MPa of H₂/CO₂.⁴⁴ Later Joó et al. carried out the hydrogenation reaction in aqueous solutions with inorganic base, such as NaHCO₃, using a series of rhodium and ruthenium complexes including [RuCl₂(tppms)₂]₂ (tppms: 3-sulfonatophenyldiphenylphosphine), [RhCl(tppms)₃], and [RuCl₂(PTA)₄] (PTA: 1,3,5-triaza-7-phosphaadamantane).⁴⁵-⁴⁸

Laurenczy et al. reported reaction mechanisms of iridium and ruthenium catalysts incorporating the water-soluble PTA ligand.⁴⁹-⁵¹ They demonstrated the formation of [η⁶-(C₆H₆)RuH(PTA)₂]⁺ as the major hydride species, and proposed a
mechanism involving hydride transfer to bicarbonate as shown in Scheme 1.6. TOFs of 237 and 409 h$^{-1}$ were obtained at 70 and 80 °C, respectively, with 10.0 MPa of H$_2$ and 1 M HCO$_3^-$.$^{[50]}$

Scheme 1.6 Possible catalyst and substrate interaction during the hydrogenation of HCO$_3^-$ in aqueous solution (Taken from ref. 50).

In 2009, Nozaki and co-workers synthesized a new Ir(III) trihydride complex bearing a PNP pincer ligand, [IrH$_3$(P3)] (P3, Scheme 1.3), for CO$_2$ hydrogenation in basic aqueous solution, and achieved the highest activity to that date at high temperature and high pressure.$^{[52, 53]}$ The use of THF as a co-solvent was necessary due to the low water solubility of the complex. This catalyst exhibited a TOF of 150000 h$^{-1}$ at 200 °C and a TON of 350000 at 120 °C over a period of 48 h under 8 MPa of H$_2$/CO$_2$ (1/1) in H$_2$O/THF (5/1). This excellent catalytic performance soon attracted considerable attention, and led to related research, including the previously mentioned Pidko’s work. Pincer ligands are known as multi-dentate ligands that strongly bind to a metal center preventing dissociation of the ligand from the metal.$^{[54-56]}$ The idea that an alkylphosphine-based pincer ligand would be an efficient electron donor may be beneficial for the hydrogenation of CO$_2$. Another inspiration comes to the importance of ligand tautomerization, e.g. the aromatization/dearomatization of the pincer ligand in Nozaki’s work.

In 2011, Hazari and co-workers reported an air-stable, water-soluble catalyst, [IrH$_3$(P4)] (P4, Scheme 1.3), for the hydrogenation of CO$_2$.$^{[57]}$ The iridium complex contains an NH group in the secondary coordination sphere. This hydrogen
bond donor, upon reaction with CO$_2$, facilitated the formation of the stable complex [Ir(OCHO)(H)$_2$(P4)] (Scheme 1.7), which was effective for CO$_2$ hydrogenation with a maximum TON of 348000 and TOF up to 18780 h$^{-1}$. Their DFT calculations indicated that CO$_2$ insertion was more thermodynamically favorable by means of stabilization of an N–H–O hydrogen bond through an outer-sphere interaction.

![Scheme 1.7 Proposed mechanism for CO$_2$ hydrogenation using IrH$_3$(P4). (Taken from ref. 57)](image)

With regard to using an earth-abundant metal instead of a noble transition metal with a pincer ligand, Milstein and coworkers focused attention on the active iron complex trans-[FeH$_2$(CO)(P$_2$)] (P$_2$, Scheme 1.3) which was capable of hydrogenating CO$_2$ with a TON of up to 790 and a TOF of up to 160 h$^{-1}$ at 80 °C under low pressure (0.6–1.0 MPa) in H$_2$O/THF (10/1).$^{[58]}$

Peris et al. performed extensive studies of water-soluble Ru and Ir complexes using bis-NHC (N-heterocyclic carbenes) ligands (Scheme 1.8).$^{[59-61]}$ A high TON of 190000 was achieved with complex [IrI$_2$(AcO)(bis-NHC)] (Scheme 1.8, right), at 200 °C under 6.0 MPa of H$_2$/CO$_2$ (1/1) in 75 h. Chelating-NHC ligands can impart a high thermal stability to the metal complexes and lead to high catalytic activity of the complex due to their electron donor character. Incorporating sul-
fonate or hydroxy substituents into the carbon side chains improves the water solubility of the complexes, and their catalytic performance for the aqueous hydrogenation of CO$_2$ was considerably improved.

![Scheme 1.8 Peris’s NHC complexes for CO$_2$ hydrogenation in water][59-61]

In the last decade, Himeda’s group has published elegant work on aqueous hydrogenation of CO$_2$ using molecular complexes with aromatic $N,N'$-chelated ligands. Inspired by the idea of electron-donating ligand being beneficial for CO$_2$ hydrogenation, they designed and synthesized a series of half-sandwich complexes \([(C_n\text{Me}_n)M(4,4-R_2\text{-bpy})\text{Cl}]^+\) (n = 5, 6; M = Ir, Rh, Ru; R = OH, OMe, Me, H; bpy = bipyridine) by introducing different electron-donating groups to the bpy ligand of the prototype catalyst \([(C_n\text{Me}_n)M(\text{bpy})\text{Cl}]\text{Cl}^-\), and applied them for the hydrogenation reaction.\[^{62-65}\] The proton-responsive hydroxy-substituted bpy ligands are deprotonated upon increasing the solution pH beyond pH 5 to 6.\[^{65}\] Deprotonation of the OH group (\(\sigma^+_{p} = -0.92\)) generates a much stronger oxyanion electron donor (\(\sigma^+_{p} = -2.30\)) because of the effect of its “keto” resonance structure (Scheme 1.9).

![Scheme 1.9 Acid–base equilibrium between hydroxy form and oxyanion form, and the resonance structures of oxyanion form][Taken from ref. 63].
Chapter 1

The Hammett plots show a good correlation between the initial TOFs and the \( \sigma_p^+ \) values of the substituents for the Ir, Rh, and Ru complexes (Scheme 1.10). The initial TOF of 5100 h\(^{-1}\) of the hydroxyl substituted complex \([\text{Cp}^*\text{Ir}(4\text{DHBP})\text{Cl}]\text{Cl}\) (4DHBP, Scheme 1.11) is over 1000 times higher than that of the unsubstituted analogue \([\text{Cp}^*\text{Ir(bpy)}\text{Cl}]\text{Cl}\) (4.7 h\(^{-1}\)) under the same conditions (80 °C, 1.0 MPa, \( \text{CO}_2/\text{H}_2 = 1 \)), further demonstrating the importance of electron-donating ligand. A high TOF of 42000 h\(^{-1}\) and TON of 190000 using \([\text{Cp}^*\text{Ir}(4\text{DHBP})\text{Cl}]\text{Cl}\) was obtained at 120 °C and 6.0 MPa. This catalyst even converts \( \text{CO}_2 \) to formate at ambient temperature (25 °C) and pressure (0.1 MPa) in 1 M NaHCO\(_3\) aqueous solution with the TOF of 7 h\(^{-1}\).

![Scheme 1.10 Correlation between initial TOFs and \( \sigma_p^+ \) values of substituents (R) for CO\(_2\) hydrogenation: M = Ir (○), Rh (●), Ru (■) (Taken from ref. 63).](image)

The Fukuzumi group also reported a proton-responsive catalyst \([\text{Cp}^*\text{Ir(N1)(OH}_2\text{)}]^{+}\) (N1, Scheme 1.11) that efficiently produces formate in 2.0 M KHCO\(_3\) aqueous solution (pH 8.8) with the TOF of 6.8 h\(^{-1}\) and TON of 100 (20 h) at 30 °C and 0.1 MPa of \( \text{H}_2 \).\(^{66}\) While most catalysts required some pressure of \( \text{CO}_2 \) in basic aqueous solution, this complex can hydrogenate HCO\(_3^-\).
In the context of constructing a second-coordination-sphere effective ligand, which is inspired by the hydrogen bond in hydrogenase, the collaboration between the Himeda and Fujita groups has led to a series of half-sandwich IrCp* complexes with ligands including nDHBP, THBPM, N2 (n = 3-6, Scheme 1.11) as catalysts for CO$_2$ hydrogenation and FA dehydrogenation under mild conditions in water. The bioinspired complexes [Cp*Ir(6DHBP)(OH$_2$)]$^{2+}$, [Cp*Ir(N2)(OH$_2$)]$^{2+}$, and [(Cp*IrCl)$_2$(THBPM)]$^{2+}$ bearing pendant OH groups exhibit significantly improved catalytic activity in CO$_2$ hydrogenation (Table 1.1).$^{[30, 62, 65, 67-71]}$

During their investigation, they found that [Cp*Ir(6DHBP)(OH$_2$)]$^{2+}$ (TOF: 8050 h$^{-1}$) showed much higher activity than [Cp*Ir(4DHBP)(OH$_2$)]$^{2+}$ (TOF: 5100 h$^{-1}$) under the same conditions. Because the electron-donating ability of the hydroxyl group at the para and ortho positions should be similar, Himeda et al. proposed that the additional rate enhancement arises from the proximity of the hydroxyl groups in 6DHBP to the metal center and a possible cooperative effect in the activation of the substrate. Experimental and computational studies on the reaction mechanism indicate that the heterolysis of H$_2$ is the RDS and the adjacent oxanions, formed from deprotonated hydroxyl groups under basic conditions, act as pendant bases and assist the heterolysis of H$_2$ (Scheme 1.12, A to D). The calculations also suggested that CO$_2$ insertion into the Ir-H bond is stabilized by a weak hydrogen bond between the hydrido ligand and deprotonated pendant base.

**Scheme 1.11** Proton-responsive ligands used for CO$_2$ hydrogenation
Scheme 1.12 Proposed mechanism for the CO$_2$ hydrogenation by [Cp*Ir(6DHBP)(OH)$_2$]$^{2+}$. Computed free energies at pH 8.3 are indicated in units of kJ mol$^{-1}$ relative to 1M A in aqueous solution and 0.1 MPa H$_2$ and CO$_2$ gases. The calculated change in free energy around the cycle is -42.0 kJ mol$^{-1}$ (Redraw from ref. 30).

1.2.4 Hydrogenation of CO$_2$ to FA

Base is needed in most of the currently reported catalyst systems. On the contrary, without adding base, hydrogenating CO$_2$ will produce FA directly and few catalytic systems are found to be effective.

In 1992, Nicholas et al. reported that the complex [Rh(NBD)(PMe$_2$Ph)$_3$]BF$_4$ (NBD: norbornadiene) serves as a precatalyst for the hydrogenation of CO$_2$ to FA at moderate temperatures in THF solution, however with TON of only 10-60/day.$^{[72]}$

Ogo and Fukuzumi et al. proposed that between pH 6-9 the real substrate for the hydrogenation reaction was not CO$_2$ but bicarbonate ion (HCO$_3^-$), because
CO₂ dissolved in H₂O shows pH-dependent equilibrium between HCO₃⁻ (pKₐ1 = 6.35 at 25 °C) and CO₃²⁻ (pKₐ2 = 10.33) (Scheme 1.13). They performed the CO₂ hydrogenation in an acidic buffer (pH = 3) using the bipyridine-derived aqua iridium/ruthenium complexes as catalysts, and were able to achieve FA without adding base, with best TOF of 27 h⁻¹ at 40 °C and 8.0 MPa.[73, 74]

\[
\text{CO}_2 + \text{H}_2\text{O} \quad \text{pK}_a = 6.35 \quad \text{HCO}_3^- + \text{H}^+ \quad \text{pK}_a = 10.33 \quad \text{CO}_3^{2-} + 2\text{H}^+
\]

\textbf{Scheme 1.13 CO}_2 \text{ hydrolysis in water}^{[73]}

In 2014, Laurenczy et al. described the direct hydrogenation of CO₂ into FA using RuCl₂(PTA)₄ (PTA = 1,3,5-triaza-7-phosphaadamantane) as catalyst, in aqueous solution and in DMSO without any additives.[75] In water, at 40 °C, 0.2 M FA can be obtained under 20 MPa; however, in DMSO the same catalyst affords 1.9 M FA. In both solvents the catalysts can be reused multiple times without a decrease in activity.

\section*{1.3 Brief Introduction of Hydrogen Energy}

As mentioned in Section 1.1, a second strategy to reduce the atmospheric CO₂ content is using renewable energy source. Moreover, it is probably the final solution for both the energy crisis and environmental problem human beings are currently facing. Hydrogen is an ideal candidate as an energy carrier for mobile fuel cell applications, as it does not have any adverse effects on the environment, and is thus expected to be a promising energy vector for the near future. Nowadays, solar-generation of hydrogen is being intensely studied, e.g. photocatalysis hydrogen production [76-79] and electrolysis of water.[80-83]

Despite the potential for production of solar-generated hydrogen, the problems
of storage and transport is often considered to be a bottleneck for realization of the hydrogen economy. Among different hydrogen storage material systems, hydrogen adsorption on porous materials, including carbonaceous materials, zeolites, and metal-organic frameworks, yields low hydrogen uptake per unit of weight in ambient conditions.\cite{84-88} Meanwhile, metal hydrides systems suffer from high weight and cost concerns; moreover, high temperatures are often required to release hydrogen.\cite{89-93} Thus the search for safe and effective liquid-phase hydrogen storage material, e.g. ammonia borane, hydrous hydrazine, cycloalkanes, nitrogen-substituted heterocycles, methanol and formic acid, is receiving much attention.\cite{94}

Therefore, among the value-added products of CO\textsubscript{2} reduction, FA is of great significance for it can also be employed as hydrogen carrier (Scheme 1.14). Although theoretically FA is not a perfect hydrogen storage medium due to its relatively small hydrogen content (4.4 wt %), it is currently still one of the best among liquid storage and transport media for H\textsubscript{2} due to its non-toxicity and excellent stability.

![Scheme 1.14 Demonstration of hydrogen energy storage using FA](image-url)
1.4 Recent Development on Homogeneous FA Dehydrogenation

In a typical hydrogen storage system using FA as the hydrogen storage material, the dehydrogenation of FA is indispensable as a companion reaction to CO$_2$ hydrogenation.$^{[95, 96]}$ The decomposition of FA has been reported with both homogeneous$^{[67, 97-102]}$ and heterogeneous catalysts.$^{[103, 104]}$ The heterogeneous decomposition of FA usually requires high temperature, and thus loses reaction selectivity and causes CO contamination by FA dehydration (eqn. 1.4), which is poisonous to the catalyst in the proton exchange membrane (PEM). For practical utilization, the CO content is generally required to be less than 10 ppm. Compared with the heterogeneous dehydrogenation of FA, homogeneous catalysis of FA dehydrogenation has been less studied, although FA has been widely used as a hydrogen donor in transfer hydrogenation in the field of organic synthesis.$^{[105-107]}$ After the pioneering work on FA dehydrogenation using homogeneous catalysts was reported by Coffey in 1967,$^{[108]}$ which gave TOF and TON of 8900 h$^{-1}$ and 11000 for FA dehydrogenation in acetic acid using IrH$_3$(PPh$_3$)$_3$ as catalyst, not much research interest in this research topic was attracted.$^{[18]}$ However in the past several years, the discovery of highly active homogeneous catalysts for FA dehydrogenation under mild conditions has stimulated renewed interest in FA as an H$_2$ carrier.

FA dehydration:

$$\text{HCO}_2\text{H (aq)} \rightleftharpoons \text{CO (g)} + \text{H}_2\text{O (g)}; \quad \Delta G^0 = -12.4 \text{ kJ/mol} \quad (1.4)$$

FA dehydrogenation:

$$\text{HCO}_2\text{H (aq)} \rightleftharpoons \text{CO}_2\text{(g)} + \text{H}_2\text{(g)}; \quad \Delta G^0 = -32.8 \text{ kJ/mol} \quad (1.5)$$

In this section, recent progress on FA dehydrogenation will be introduced, highlighting the most efficient catalytic systems under various reaction conditions. Although the dehydrogenation of FA is thermodynamically favorable (eqn. 1.5), the addition of base or other additives is widely employed. Since FA dehydro-
genation is the reverse reaction of the hydrogenation of CO$_2$, a catalyst could be effective to both reactions and this section is relevant to section 1.2.

1.4.1 FA dehydrogenation in organic solution with additives

In 2008, Beller et al. reported the dehydrogenation of a FA/triethylamine (FA/Et$_3$N) azeotropic mixture, which evolved H$_2$ and CO$_2$ exclusively, using ruthenium-based catalysts with triphenylphosphine-type ligands.$^{[109]}$ The high initial TOF of 2700 h$^{-1}$ (initial 20 min) and a TON of 890 (2 h) at 40 °C were obtained with the commercially available ruthenium complex [RuCl$_2$(PPh$_3$)$_3$]. The effects of different phosphine ligands, amines, and ruthenium complexes on catalytic activity and durability were then investigated,$^{[110]}$ and a better combination of [RuCl$_2$(C$_6$H$_6$)$_2$] with a bidentate phosphine ligand P5 (Scheme 1.3) was identified. Because the presence of an amine is beneficial for hydrogen production, loss of the amine by volatilization led to a decrease in reaction rate. Thus using a less volatile amine, DMOA (dimethyloctylamine), resulted in the highest TON of 1000000 for 1080 h at 25 °C.$^{[111]}$ During the course of the reaction, the CO concentration did not exceed 2 ppm.

Later, based on this catalytic system, Wills reported dehydrogenation of FA/amine mixtures with [RuCl$_2$(DMSO)$_4$].$^{[112, 113]}$ Although CO (190–440 ppm) was detected by GC, a high TOF of 18 000 h$^{-1}$ was observed at 120 °C. They also reported long-term operation under continuous flow conditions. Gas production rates as high as 1.5 L min$^{-1}$ and total gas production of 462 L were obtained during 6 h.

Milstein et al. applied iron-based PNP pincer complex [(P$_2$)Fe(H)$_2$(CO)] (P2, Scheme 1.3) as catalysts for the dehydrogenation of FA.$^{[114]}$ The reaction in dioxane in the presence of 50 mol % Et$_3$N at 40 °C led to a total TON of 100000 in 10 days. The poor activity in water is likely due to the low solubility of the catalyst.

<sup>a</sup> Insignificant digits are rounded;  <sup>b</sup> n.d.: not detected (or not reported)
Berben et al. reported that aluminum pincer complexes with the-phenyl-substituted bis(imino)pyridine ($\text{Ph}_2\text{IP}$) ligands showed the high initial TOF of 5200 h$^{-1}$ in Et$_3$N/THF at 65 °C without CO production.$^{[115]}$ They characterized each of the elementary steps in the catalytic cycle. The complex ($\text{Ph}_2\text{IP}$)Al(THF)H reacted with 3 equiv. of HCO$_2$H to afford the doubly protonated species as a resting state. They proposed that the β-hydride elimination from the doubly protonated form affords an Al–H intermediate, which smoothly releases H$_2$ upon protonation (Scheme 1.15).

Scheme 1.15 Proposed mechanism for FA dehydrogenation by ($\text{Ph}_2\text{IP}$)Al(THF)H (based on ref. 115)

In 2013, our group (Xiao) reported that the N^C cyclometallated iridium(III) complexes derived from 2-aryl imidazoline ligands were found to be excellent catalysts for the decomposition of FA together with NEt$_3$ to give H$_2$ and CO$_2$ under mild conditions with no CO formation.$^{[116]}$ The fine tuning of catalyst structure led to a high TOF of 147000 h$^{-1}$ at 40 °C. The presence of the remote γ-NH unit in the ligand was shown to be essential for catalytic activity, without which no reaction occurs. Mechanistic studies suggest that the dehydrogenation is rate-limited by the step of hydride protonation, which is made feasible by the γ-NH unit on the imidazoline ring via an unusual form of long-range metal–ligand
bifunctional catalysis involving FA-assisted proton hopping (Scheme 1.16).

Scheme 1.16 Proposed catalytic cycle for the dehydrogenation of HCO₂H (Taken from ref. 116).

As mentioned previously, the PNP-pincer complex [RuH(Cl)(CO)(P₂)] reported by the Pidko group is highly active for CO₂ hydrogenation as well as the FA dehydrogenation in DMF/Et₃N. A high TOF of 257000 h⁻¹ and TON of 1063000 (for 5 h) were achieved with continuous addition of FA at 90 °C in separate experiments.²² The loss of volatile Et₃N at 90 °C is a major problem for this system.

Hazari and Schneider et al. reported Lewis acid (LA) assisted FA dehydrogenation catalyzed by iron-based PNP pincer complexes [(⁴PNH₃)Fe(CO)H(Cl)] (⁴PNH₃ = HN(CH₂CH₂(PR₃))₂; R = iPr or Cy, Scheme 1.17) in dioxane without the need for an external base.¹¹ The presence of LA cocatalysts provided the high TOF of 196700 h⁻¹ and TON of 1000000 in 9.5 h in dioxane at 80 °C. Unfortunately, CO (less than 0.5%) was detected in the produced gas mixture. Scheme 1.17 shows the LA assisted decarboxylation of a key iron formate intermediate.
Scheme 1.17 Proposed pathway for decarboxylation in the absence (a) and presence (b) of a LA. (Redraw from ref. 117)

1.4.2 FA dehydrogenation in organic solution without additives

In 2011, Beller et al. reported an active iron catalyst system for the liberation of H₂ from FA. Applying 0.005 mole % of Fe(BF₄)₂·6H₂O and P(CH₂CH₂PPh₂)₃ to a solution of FA in propylene carbonate, with no further additives or base, affords TOF up to 9425 per hour and a TON of more than 92000 at 80°C. Subsequently, they reported the results of a detailed investigation of the effect of various ligands, metal salts, solvent, and additives (e.g., chloride, fluoride, formate). The addition of water resulted in a decrease in catalytic activity.

Reek et al. reported the base-free FA dehydrogenation using an iridium complex bearing a phosphine-functionalized sulfonamide (bisMETAMORPhos) ligand, the anionic form of which can function as an internal base. The system produced CO-free H₂ with the TOF of 3270 h⁻¹ in dioxane at 85 °C. The initial Ir(I) complex underwent a slow proton transfer from the neutral ligand arm to the metal, resulting in the formation of the active Ir(III)–H complex (Scheme
1.18). The bifunctional ligand allowed the direct hydride transfer from FA to the Ir center rather than the common β-hydride elimination. It also facilitated the release of hydrogen (Scheme 1.19).

![Scheme 1.18 Formation of active species for complex Ir(bisMETAMORPhos) via internal proton transfer. (Redraw from ref. 120)](image)

![Scheme 1.19 Proposed mechanism for the cooperative dehydrogenation of FA. (Redraw from ref. 120)](image)

### 1.4.3 Aqueous dehydrogenation of FA with additives

In 2008, Laurenczy et al. reported an aqueous system of HCO$_2$H/HCO$_2$Na for FA dehydrogenation using a ruthenium catalyst with a water-soluble phosphine ligand, for example, tppts (tris(3-sulfonatophenyl)phosohine).\textsuperscript{[122, 123]} The TOF of 460 h$^{-1}$ was observed at 120 °C without the use of an organic amine, but instead a small amount of HCO$_2$Na was used for the activation of the catalyst. Constant hydrogen generation with total TON > 40000 was achieved by continuous addition of FA.
The Fukuzumi group has made early effort on aqueous dehydrogenation of FA using water soluble iridium/ruthenium complexes. In 2008, they reported FA dehydrogenation with half-sandwich complexes bearing bidentate 2,2’-bipyridine derivatives.\cite{124} With the addition of HCO$_2$Na, the system gave a TON of 30 in 2 h at pH 3.8 and 20 °C. They also reported a water soluble heterodinuclear iridium−ruthenium complex [Cp*Ir(OH)$_2$(bpm)Ru(bpy)$_2$(SO$_4$)$_2$ (bpm: 2,2’-bipyrimidine), which gave an initial TOF of 426 h$^{-1}$ at room temperature in HCO$_2$H/HCO$_2$Na (pH 3.8).\cite{125} More recently, they demonstrated the dehydrogenation of FA using a C,N-cyclometalated iridium complex bearing a proton-responsive carboxylic acid (N1, Scheme 1.11), which was also applied for the hydrogenation of CO$_2$ as previously mentioned, and a maximum TOF of 1880 h$^{-1}$ was obtained at pH 2.8 and 25 °C.\cite{66}

The iridium complexes with aromatic N,N’ ligands developed based on the collaboration between the Himeda and Fujita groups not only catalyze the hydrogenation of CO$_2$ as described in section 1.2, but also are effective catalysts for the dehydrogenation of FA.\cite{67,126} [(Cp*IrCl)$_2$(THBPM)]$^{2+}$ catalyses the release of H$_2$ and CO$_2$ (1:1) from aqueous HCO$_2$H/HCO$_2$Na mixture with a TOF of 228000 h$^{-1}$ at 90 °C and TON of 308000 at 80 °C, the highest TOF and TON reported by then.\cite{67}

**1.4.4 Aqueous dehydrogenation of FA without additives**

In 2009, Himeda demonstrated the efficient evolution of CO-free hydrogen by the decomposition of FA using an iridium catalyst with 4DHBP (Scheme 1.11) as a ligand in H$_2$O.\cite{127} A high catalytic activity (TOF: 14000 h$^{-1}$ at 90 °C) and an almost complete consumption of FA were obtained without any additives. Furthermore, it was found that hydrogen could be generated even at elevated pressures.

The iridium catalyst [(Cp*IrCl)$_2$(THBPM)]$^{2+}$ reported by Hull, Himeda and Fu-
jita et al. can also dehydrogenate FA in water without the addition of base, albeit giving a lower TOF of 12000 h\(^{-1}\) at 60 °C.\[^{67}\]

In 2014, Wang, Himeda and coworkers reported an iridium-biimidazole complex for the FA dehydrogenation, giving a TOF of 34000 h\(^{-1}\) at 80 °C, which was the highest TOF reported for FA dehydrogenation in water without bases or additives by then.\[^{128}\]

1.5 Conclusions and Objectives of This Thesis

1.5.1 Literature summary

Homogeneous hydrogenation of CO\(_2\) to FA/formate and the dehydrogenation of FA/formate have been explored for decades, and they are gaining more and more attention from the beginning of this century due to both energy and environmental concerns. Because the hydrogenation of CO\(_2\) is reversible, generally a catalyst which is effective for CO\(_2\) hydrogenation can also catalyze the dehydrogenation of FA, although it may be more effective for one direction than the other.\[^{32, 66, 67, 129, 130}\]

Dozens of homogeneous catalyst systems based on metal complexes of Ir, Ru, Rh, Fe, Co, etc. have appeared for CO\(_2\) hydrogenation and FA dehydrogenation, and the catalytic reactivity has been improved dramatically. For example, as described in section 1.2.3, Nozaki and co-workers reported the iridium trihydride complex [IrH\(_3\)(P3)] for CO\(_2\) hydrogenation to exhibit a TOF of 150000 h\(^{-1}\) at 200 °C and a TON of 3500000 at 120°C over a period of 48 h under 8.0 MPa of H\(_2\)/CO\(_2\) (1/1) in H\(_2\)O/THF (5/1). Pidko et al. reported that [RuH(Cl)(CO)(P2)] provided a TOF as high as 1100000 h\(^{-1}\) for the hydrogenation of CO\(_2\) in DMF using DBU as a base at 120 °C and 4.0 MPa of H\(_2\)/CO\(_2\) (3/1). For the dehydrogenation of FA/formate, Pidko’s catalyst [RuH(Cl)(CO)(P2)] also gives a high TOF of
257000 h\(^{-1}\) and TON of 1063000 (for 5 h) at 90 °C in DMF/ Et\(_3\)N. These reports represented the best results by the time the objective of this thesis was set and some remain the highest to date.

The above mentioned results have been obtained in organic solvents. Other groups, like those of Laurenczy, Beller, Fukuzumi, Himeda and Fujita, have made effort to accomplish the hydrogenation of CO\(_2\) and FA dehydrogenation in more environmentally benign solution, i.e. water, under milder conditions, and good reactivity has been achieved. Particularly, Fujita et al. reported the pH sensitive iridium complex [(Cp*IrCl)\(_2\)(THBPM)]\(^{2+}\) for this reversible reaction with remarkable TONs and TOFs. At high pH (2 M KHCO\(_3\)), CO\(_2\) hydrogenation rates of 70 h\(^{-1}\) (25 °C and 0.1 MPa) and 53800 h\(^{-1}\) (80 °C and 5.0 MPa) were observed. At low pH, [(Cp*IrCl)\(_2\)(THBPM)]\(^{2+}\) can decompose FA or formate to give CO-free H\(_2\) and CO\(_2\), and a high TOF of 228000 h\(^{-1}\) at 90 °C and TON of 308000 at 80 °C were obtained in 1M HCO\(_3\)H/HCO\(_2\)Na (1:1, pH 3.5).

Apart from the solvent problem, both CO\(_2\) hydrogenation and FA dehydrogenation frequently rely on the addition of additives, such as bases and LA, which is against the principle of atom economy. The drawbacks of these catalytic systems are obvious: i) the employment of ungreen organic solvents; ii) the cost due to the addition of additives and product separation. At present, only a few catalytic systems have been reported to be active for CO\(_2\) hydrogenation and FA dehydrogenation in water without bases or additives.\([67, 73-75, 127, 128]\) However, the reactivity is rather low.

### 1.5.2 Thesis objectives

From the viewpoint of practical application, simple and highly effective catalytic system is always desired. However there’s still a great gap between lab research and industry production and the development of efficient homogeneous catalyst
remains necessary and challenging. Targeting at the current problems, the main objective of this thesis is to develop efficient homogeneous catalyst systems for the hydrogenation of CO$_2$ to FA and the FA dehydrogenation under mild and environmentally benign conditions. The key issue is the catalyst development and especially the design of ligands, which involves several factors, such as electronic property and water solubility, etc.

Based on the literature research and our group’s previous work on hydrogenation/transfer-hydrogenation (Xiao),[116, 131-134] this thesis focuses on the homogeneous catalytic hydrogenation of CO$_2$ and FA dehydrogenation using different metal complexes, and the study is carried out in the following aspects:

1. Chapter 2 reports homogeneous hydrogenation of CO$_2$ to formate catalyzed by N$^\text{C}$ cyclometallated half-sandwich iridium catalysts;
2. In chapter 3, new ligand type is exploited and base-free aqueous hydrogenation of CO$_2$ has been realized using iridium catalysts with non-aromatic $N,N'$ diimine ligands;
3. Chapter 4 applies this Ir-$N,N'$ diimine catalyst to the FA dehydrogenation, and delightfully the highest TOF and TON values ever reported under similar conditions were achieved;
4. Chapter 5 presents the study of FA dehydrogenation using commercially available catalyst [RhCp*Cl$_2$]$_2$ in the presence of simple halide ions.
Chapter 2 Hydrogenation of CO$_2$ to Formate Catalyzed by Cyclometallated Ir-N\(^{\text{C}}\) Complexes
2.1 Introduction

Homogeneous hydrogenation of CO₂ into formate/FA is an ideal way to utilize CO₂ and to store H₂; but it has been a long-standing challenge for the activation of CO₂. In CO₂ molecule, the C=O bond length is around 116.3 pm, which falls in between the C=O bond in carbonyl compounds of ca 123 pm and the triple C≡O bond of 112.8 pm. Thus CO₂ has partial triple bond character and is difficult to be activated. The catalyst library for the homogeneous hydrogenation of CO₂ to formate has been growing progressively since the first one, [RhCl(PPh₃)₃], was reported in 1976 by Inoue et al.[27] Dozens of transition-metal complexes based on ruthenium,[40-42, 75] rhodium,[72, 135] iridium,[30, 52, 57, 62, 70, 136] ion,[35, 58, 137] cobalt[31, 36] and nickel[138] have been reported to exhibit activity for this reaction. However, most of these catalyst systems show high activity only at harsh conditions such as high temperature and high pressure, which is unfavorable from the practical point of view. A number of catalysts can work under mild conditions but with moderate reactivity.[30-32, 45, 69, 73, 74, 135] For example, Fujita et al. reported a dinuclear iridium complex with a bipyrimidine ligand for CO₂ hydrogenation to formate, giving a TOF of 15700 h⁻¹ and a TON of 153000 at 50 °C under the pressure of 4.0 MPa in 2 M KHCO₃ aqueous solution.[67] Therefore, developing catalysts for mild and efficient hydrogenation of CO₂ to formate is still challenging.

In the early years, the research of Jessop and Sakaki et al. had indicated that the strong electron-donating ability of the ligand, e.g. phosphine ligands, leads to high activity of such a complex in CO₂ hydrogenation.[28, 29] A few more reports subsequently followed. Peris et al. performed CO₂ hydrogenation using water-soluble Ru and Ir complexes bearing bis-NHC (N-heterocyclic carbenes) ligands, and high catalytic activity was obtained due to the electron donor character of the
NHC ligand.\textsuperscript{[61]} Himeda and Fujita et al. reported a series of half-sandwich iridium bipyridine complexes \([\text{Cp}^*\text{Ir}(4,4'-(R)_2\text{-bpy})(\text{OH}_2)]\text{SO}_4\) and \([\text{Cp}^*\text{Ir}(6,6'-(R)_2\text{-bpy})(\text{OH}_2)]\text{SO}_4\) \((R = \text{OH, OMe, Me, H})\) by introducing different electron-donating groups to the bpy ligand. For the hydrogenation of CO\textsubscript{2} using these complexes as catalyst, they also found that stronger electron-donating substituents lead to higher reaction rates.\textsuperscript{[63]}

N^C cyclometallated metal complexes have been shown to be excellent catalysts for the reduction of C=O bond.\textsuperscript{[139, 140]} The Xiao group has been working on hydrogenation/transfer hydrogenation for many years, and have reported that N^C cyclometallated \([\text{Cp}^*\text{IrCl}]\) imido complexes derived from acetophenone imines are exceptionally active catalysts for the reduction of imines.\textsuperscript{[131-134]} The N^C bidentate ligand is expected to be more electron-donating compared with the bipyridine type N^N ligand; thus the N^C cyclometallated \([\text{Cp}^*\text{IrCl}]\) complex could be effective catalyst for the hydrogenation of CO\textsubscript{2}.

More importantly, inspired by the hydrogenation/transfer hydrogenation work and the observation of gas evolution during the transfer hydrogenation reaction using the 5:2 FA/Et\textsubscript{3}N azeotrope (F/T) as hydrogen source with the cyclometallated iridium complex, the Xiao group has designed a type of N^C cyclometallated iridium(III) complexes bearing phenylimidazoline ligands and found that they are excellent catalysts for the dehydrogenation of FA,\textsuperscript{[116]} giving TOF of up to 147000 h\textsuperscript{-1} at 40 °C in F/T azeotrope. These results prompted us to investigate the hydrogenation of CO\textsubscript{2} using this type of cyclometallated iridium complexes.

\section*{2.2 Hydrogenation of CO\textsubscript{2} to Formate with Ir-N^C Complex}

\subsection*{2.2.1 Initial catalyst screening}

The CO\textsubscript{2} hydrogenation work started from screening of iridium catalysts formed
from [IrCp*Cl₂]₂ and phenylimidazoline-type ligands, complexes 1-7, which have been used for FA dehydrogenation[116] and transfer hydrogenation[141] previously. The hydrogenation reactions were carried out in a KOH/MeOH solution at 4.5 MPa of CO₂/H₂ (2:1) and 80 °C for 16 h, and the results are summarized in Scheme 2.1. ¹H NMR spectra confirmed the product to be potassium formate exclusively (Appendix, Scheme A.1). The amount of produced formate was determined by ¹H NMR using sodium p-toluenesulfonate as internal standard (Appendix, Scheme A.1).

Under the given reaction conditions, no reactivity was detected without catalyst. The iridium dimer [IrCp*Cl₂]₂ itself hardly shows any activity (TON = 6, Scheme 2.1) for the hydrogenation of CO₂, which indicates the importance of the ligand, comparing with complexes 1-7.

**Scheme 2.1** Hydrogenation of CO₂ using N°C cyclometallated iridium complexes 1-7.

Reaction conditions: complex 1-7 (3.0 μmol), 1.0 M KOH MeOH solution (10.0 mL), 4.5 MPa CO₂/H₂ (1:2), 80 °C, 16 h. Reactions were carried out in a stainless steel autoclave (100 mL) with a glass inner. *5.0 μmol of [IrCp*Cl₂]₂.

Ligand structure influences the catalytic activity greatly. Complexes 1-3 gave
TONs of 1587, 476, and 1302, respectively, for the hydrogenation of CO$_2$ to formate. Changing the imidazoline ring of the 2-imidazolinyI ligand in complex 1 to the oxazoline ring (precatalyst 2) and replacing the NH proton in the 2-imidazolinyI ligand with acetyl group (precatalyst 3) both led to less active catalysts, suggesting that the γ-NH unit on the N^C ligand facilitates this reaction. It is noteworthy that complexes 2 and 3 both show no reactivity towards FA dehydrogenation,\textsuperscript{[116]} whilst they can hydrogenate CO$_2$. This result implies that the CO$_2$ hydrogenation reaction and FA dehydrogenation reaction may undergo different reaction pathways using these cyclometallated Ir-N^C catalysts, especially considering the huge difference in reaction conditions, or the former is easier to occur.

By introducing bulky substituents onto the ligand, complex 4 shows increased TON (2210) compared with 1, which is consistent with the FA dehydrogenation result.\textsuperscript{[116]} Complex 5 with electron withdrawing group on the phenyl ring and complex 6 with electron donating group on the phenyl ring both increase the reactivity, giving TONs of 2987 and 2442, respectively. These results indicate that the substituent’s electron property doesn’t influence the reaction rate in a simple way or it may have no influence at all, which is unexpected. One possible explanation is that the substituent on the phenyl ring is not much involved in the HOMO/LUMO of the iridium complex (\textit{vide infra}). When complex 7 with three methoxy groups on the ligand was applied for the hydrogenation of CO$_2$, a much higher TON of 3330 was obtained. The following reaction condition optimizations were performed using complex 7 as catalyst.

\textbf{2.2.2 Optimization of reaction conditions}

The reaction was studied under various reaction times, and Scheme 2.2 shows that the reaction rate slows down in about 6 h. Thus for experimental convenience, the subsequent hydrogenation reactions were conducted either for 6 h or 16 h.
Scheme 2.2 Formate production from CO$_2$ hydrogenation at different reaction time.

Reaction conditions: complex 7 (3.0 μmol), 1.0 M KOH/MeOH solution (10.0 mL), 4.5 MPa CO$_2$/H$_2$ (1:2), 80 °C. Reactions were carried out in a stainless steel autoclave (100 mL) with a glass inner.

$^a$ Reaction conditions: complex 7 (3.0 μmol), 4.5 MPa CO$_2$/H$_2$ (1:2), 80 °C, 6 h. Reactions were carried out in a stainless steel autoclave (100 mL) with a glass inner.

Different bases (2 M) were then screened for the iridium catalyzed CO$_2$ hydrogenation as shown in Table 2.1. Entries 1-3 show the superior performance of NaOH (TON: 4450) and KOH (TON: 4255) compared with LiOH (TON: 3399). Since CsOH was purchased as a water solution, the hydrogenation reaction was conducted in a mixture solution of water and methanol. The TON further in-
creased to 6545 and the reaction approached approximately full conversion in terms of the amount of base used (Table 2.1, entry 4). The higher TON could be due to water playing some role in this reaction. When again using KOH as the base, a TON of 5500 (Table 2.1, entry 5) was attained in the mixture solution of MeOH/H₂O (6.5/3.5 mL), which is higher than that of the reaction carried out in pure methanol. Thus the impact of water on the hydrogenation reaction was investigated next.

With different volume ratios of MeOH/H₂O (total 10.0 mL), the hydrogenation of CO₂ was studied using complex 7 and the cheaper base KOH. The catalyst loading was lowered to 0.5 μmol to avoid high conversion. As displayed in Scheme 2.3, the TON for formate generation varies greatly with different ratios of MeOH/H₂O, with TON reaching the highest value (29325) when the ratio is around 1:1.

![Scheme 2.3 TON of formate production from CO₂ hydrogenation in MeOH/H₂O solution. Reaction Conditions: complex 7 (0.5 μmol), 1.0 M KOH/MeOH/H₂O mixture solution (total volume 10.0 mL), 4.5 MPa CO₂/H₂ (1:2), 80 °C, 16 h. Reactions were carried out in a stainless steel autoclave (100 mL) with a glass inner.](image)

The effect of water in homogeneous hydrogenation of CO₂ has been noted and
investigated.\cite{18, 27, 28, 75, 142} In organic solvents, small amount of added water can enhance the reaction rates,\cite{72} and its function was assumed to be stabilizing the transition state through an H-bonding interaction between the coordinated water molecule and the oxygen of the approaching CO\(_2\) in the insertion step of CO\(_2\) to metal hydride. In basic aqueous solution, a kinetic isotopic effect (KIE) study with a proton-responsive iridium complex for CO\(_2\) hydrogenation to formate demonstrates the involvement of water in the rate-determining step to accelerate the heterolysis of H\(_2\).\cite{69} Thus the hydrogenation of CO\(_2\) may be more favorable in water. However these cyclometallated Ir-N^\(\gamma\)C complexes are not soluble in water. Effort was subsequently made to increase the water solubility of catalysts and more studies were performed.

### 2.2.3 Further development of catalyst

In the MeOH/H\(_2\)O (1:1) mixture solution of KOH, some previously screened complexes and newly developed catalysts were tested again for CO\(_2\) hydrogenation reaction, but at a lower temperature of 40 °C (Scheme 2.4). \(^1\)H NMR spectra also confirmed the product to be potassium formate exclusively (Appendix, Scheme A.2). The amount of produced formate was detected by ion chromatography and no reactivity was detected without catalyst. In this section, TOF was adopted to describe the activity of the catalysts.

Complexes 1-3 and 10 give TOFs of 650 h\(^{-1}\), 360 h\(^{-1}\), 250 h\(^{-1}\) and 140 h\(^{-1}\), respectively. Moreover, replacing the NH proton in the 2-imidazolinyl ligand with either electron withdrawing acetyl group (precatalyst 3) or electron donating methyl group (precatalyst 10) both led to less active catalysts compared with complex 1. The conclusion is similar as discussed in section 2.2.1, which is that the \(\gamma\)-NH unit on the N^\(\gamma\)C ligand shows its superiority for this reaction but is not indispensable.
Scheme 2.4 Hydrogenation of CO\textsubscript{2} using cyclometallated Ir-N\textsuperscript{C} complexes 1-6 and 8-10.

Reaction conditions: 0.2 μmol of complex, 1.0 M KOH/MeOH/H\textsubscript{2}O (1:1) solution (10.0 mL), 5.0 MPa CO\textsubscript{2}/H\textsubscript{2} (1:1), 40 °C, 1 h. Reactions were carried out in a stainless steel autoclave (300 mL) with a glass inner.

Under such reaction conditions, complexes 4-6 show better performance than 1, giving TOFs of 1130 h\textsuperscript{-1}, 3230 h\textsuperscript{-1} and 4110 h\textsuperscript{-1}, respectively. This TOF difference also suggests that no unambiguous conclusion can be drawn concerning the relationship between the electronic property of substituent and the catalytic reactivity. Noteworthy is that, the TOF value of 4110 h\textsuperscript{-1} obtained with complex 6 bearing a relatively hydrophilic methoxy group on the ligand is considerably higher than that of complex 5, in the mixture solution of MeOH/H\textsubscript{2}O, encouraging us to incorporate hydrophilic ligand into the cyclometallated Ir-N\textsuperscript{C} complexes.

Since water as solvent plays an important role in this reaction and these complexes are water-insoluble, complex 8 and 9 based on the backbone of complex 6 were designed to investigate the ligand hydrophilicity effect on reactivity. Complex 8 and 9 were synthesized using the same method as complex 6, and each of them consists of two inseparable regioisomers, 8a/8b and 9a/9b, resulting from
the competing cyclometallation of the C$_2$ and C$_4$ phenyl rings in the NaOAc-mediated cyclometallation reaction (Scheme 2.5; for characterizations, see experimental section). As expected, complex 8 with a poly ethylene glycol type substituent (-O(CH$_2$CH$_2$O)$_2$CH$_3$) on the cyclometallated aryl ring shows a higher TOF of 5720 h$^{-1}$ compared with complex 6. In contrast, complex 9 with a long alkyl chain (-O(CH$_2$)$_{17}$CH$_3$) on the cyclometallated aryl ring hardly shows any activity under the otherwise identical conditions. These results indicate that catalyst with hydrophilic ligand show better catalytic activity than catalyst with hydrophobic ligand.

Scheme 2.5 Synthesis of complex 8 and 9

The reason for the significant difference in catalytic activity for CO$_2$ hydrogenation between 8 and 9 was further investigated. $^1$H NMR results show a small composition difference between complexes 8 and 9 (8a:8b = 1.5:1, 9a:9b = 1.3:1), which is not likely to cause such great difference in catalytic activity.

Scheme 2.6 shows the UV-Vis absorption spectra of complex 6, 8 and 9 as well as their parent ligands L6, L8 and L9. The resemblance of the absorption curves among the three complexes suggests the similarity of their electronic properties.
Scheme 2.6 UV-Vis absorption spectra of complex 6, 8, 9 and ligands L6, L8, L9 (50 mM) in CH₂Cl₂ (DCM)

Scheme 2.7 HOMO (-1) and LUMO (+1) models of complex 6, 8 and 9.

The calculations were performed with the GAUSSIAN09 package.¹⁴³ The Becke three parameters hybrid functional with the Lee-Yang-Parr correlation functional (B3LYP) was chosen for taking into account the exchange and correlation effects of electrons, and the 6-31+G(d) basis set was used for all the atoms.¹⁴⁴,¹⁴⁵ The contours of frontier molecular orbitals are visualized with GaussView software.¹⁴⁶ The calculation was performed by Dr./Prof. Xin Zhou.
The DFT calculation (Scheme 2.7) results also show that the -OMe, -O(CH₂CH₂O)₂CH₃ and -O(CH₂)₁₇CH₃ substituents on the cyclometallated aryl ring of complex 6, 8 and 9 are not much involved in the HOMO or LUMO of these molecules. In addition, the frontier orbitals of these complexes are similar in shape. These results indicate that the huge difference in CO₂ hydrogenation activity between 8 and 9 is not likely due to the electronic effect of the ligand.

Meanwhile, the hydrophilicity of complex 8 and 9 was tested by means of the contact angle measurement. The water contact angle for complex 8 is 80.97°, while the value for complex 9 is 123.4° (Scheme 2.8), showing that complex 8 is more hydrophilic than complex 9. Thus a hydrophilic ligand is likely beneficial for this reaction under the given reaction conditions.

![Scheme 2.8 Water contact angle measurement demonstration for 8 (left) and 9 (right).](image)

During the initial reaction conditions screening, solvent composition was found to affect the reactivity to a great extent. As displayed in Scheme 2.9, using complex 8 as catalyst, the TOF for formate generation obtained in a mixture solution of MeOH/H₂O shows a similar trend, with TOF reaching the highest value (8140 h⁻¹, 60 °C) when the amount of methanol and water is equal. As discussed in section 2.2.2, this reaction is favorable in water and this result might be a compromise of the reactivity and the solubility of the catalyst.
Scheme 2.9 Hydrogenation of CO$_2$ with different MeOH/H$_2$O ratios.

Reaction conditions: complex 8 (0.2 μmol), 2.0 M KOH/MeOH/H$_2$O solution (10.0 mL), 5 MPa CO$_2$/H$_2$ (1:1), 60 °C, 1 h. Reactions were carried out in glass vials placed in a stainless steel autoclave.

General reaction conditions: complex 8 (0.2 μmol), co-solvent/H$_2$O (1:1) solution (10.0 mL), 1.0 M KOH, 5 MPa CO$_2$/H$_2$ (1:1), 40 °C, 1 h. TOF value is the rate for the initial 1 h; thus TON and TOF have the same values here.$^a$ TON/TOF value was obtained with blank reaction result deducted (refer to $^b$).$^b$ Reaction carried out without catalyst - blank reaction.

In addition, this reaction was also conducted in mixtures of water and other
co-solvents (Table 2.2). Reactions in tetrahydrofuran (THF), dimethylformamide (DMF), dimethylsulfoxide (DMSO) and ethylene glycol (MW = 200) all show lower activities compared with MeOH.

Reaction conditions: complex 8 (0.2 μmol), MeOH/H$_2$O (1:1) solution (10.0 mL), 1.0 M KOH, 1 h. TOF value is calculated using the first 1 h data.

Figure 2.10 Arrhenius plot of formate producing rate for the hydrogenation of CO$_2$.

Reaction conditions: complex 8 (0.2 μmol), MeOH/H$_2$O (1:1) solution (10.0 mL), 1.0 M KOH, 5 MPa CO$_2$/H$_2$ (1:1), 20, 30, 40 °C, 1 h. Reactions were carried out in a stainless steel autoclave (300 mL) with a glass inner.
The catalytic hydrogenation of CO$_2$ to formate using complex 8 was investigated under various conditions. The rate for CO$_2$ hydrogenation increases with temperature rise (Table 2.3, entry 1-3). The temperature dependence of initial TOFs follows the Arrhenius equation (Scheme 2.10) and the estimated apparent activation energy (Ea) for CO$_2$ hydrogenation is 76 kJmol$^{-1}$, which is in the range of noble metal catalyzed CO$_2$ hydrogenation reactions.$^{[30,49]}$ Changes in the ratio of CO$_2$:H$_2$ from 1:1 to 2:3 and 3:2 result in a slight decrease in reactivity (Table 3, entries 3-5).

Reaction conditions: complex 8 (0.2 μmol), 1.0 M KOH/MeOH/H$_2$O (1:1) solution, 5.0 MPa CO$_2$/H$_2$ (1:1). TOF value is calculated using the first 1 h data. $^a$ TOF value is calculated using the 0.5 h data. $^b$ 4.0 μmol of complex 8, 2.0 M KOH, 20.0 mL reaction solution. $^c$ 2.0 M KOH. $^d$ 0.1 μmol of complex 8. Entries 1-4: Reactions were carried out in a stainless steel autoclave (300 mL) with a glass inner. Entries 5, 6: Reactions were carried out in a stainless steel autoclave (300 mL) without glass inner and negligible amount of formate was detected without catalyst.

When the reaction solution was expanded to 50 mL, a higher initial TOF of 9820 h$^{-1}$ was obtained at 40 $^\circ$C and the turnover number reached 59420 after 14 hours (Table 2.4, entry 2, 3). Using 4.0 μmol of complex 8 at 40 $^\circ$C, the final con-
centration of formate reached 0.7 M (Table 2.4, entry 4). When the temperature was increased to 80 °C, the initial TOF increased to 57330 h\(^{-1}\) (entry 5), and a TON of 102200 was obtained after 12.5 h (Table 2.4, entry 6). These results are comparable with the highest reactivity reported under similar mild conditions.\[67\]

### 2.3 Summary

In summary, the cyclometallated Ir-N\(^{\#}\)C complexes show good performance for CO\(_2\) hydrogenation to formate, extending the ligand type that could be used for the hydrogenation of CO\(_2\) to FA/formate.

During the catalyst screening and reaction conditions optimization, it was found that the hydrogenation of CO\(_2\) with the phenylimidazoline-type cyclometallated Ir-N\(^{\#}\)C complexes shows faster rates in a MeOH/H\(_2\)O (around 1:1) mixture solution than in pure solvent, and the catalyst bearing more hydrophilic ligand (complex 8) is remarkably effective for this reaction compared with catalyst containing hydrophobic ligand (complex 9). Using 0.2 μmol of complex 8, a TOF of 9820 h\(^{-1}\) was obtained at 40 °C under a total pressure of 5.0 MPa, and the TON could reach 102200 when temperature increased to 80 °C.

However, the attempt to synthesize more water-soluble cyclometallated Ir-N\(^{\#}\)C complexes (Scheme 2.11) failed; thus the organic solvent-free hydrogenation of CO\(_2\) under mild conditions couldn’t be fully achieved with this type of catalyst.

![Scheme 2.11 Idea of synthesizing more water-soluble cyclometallated Ir-N\(^{\#}\)C complex](image)

These complexes are of great significance not only for they can convert CO\(_2\) into formate, but also because they provides a potential way for hydrogen storage
considering their excellent performance towards dehydrogenation of FA to give hydrogen under mild conditions.

2.4 Experimental Section

2.4.1 General information

**Instruments**: NMR spectra were recorded on a Bruker Avance-400 spectrometer. The concentration of formate was measured by SHINEHA CIC-100 ion chromatograph with Shodex IC SI-52 4E column using Na$_2$CO$_3$ solution (3.6 mM) as the eluent. HRMS data were obtained from a Finnigan MAT 95 system. UV-Vis absorption spectra were recorded with SHIMADZU UV-2550. Contact angle measurement was performed by the Energy Research Resources Division of Dalian National Laboratory for Clean Energy. X-ray diffraction analysis was performed by the State Key Laboratory of Organometallic Chemistry (Shanghai).

**Chemicals**: Dry dichloromethane (DCM), hexane, methanol, tetrahydrofuran, and dimethylformamide were purchased from J&K. [Cp*IrCl$_2$]$_2$ was purchased from Strem Chemicals Inc. KOH was purchased from Acros. All other commercial compounds were purchased from Sigma-Aldrich Co. or Alfa Aesar and used without further purification. Solvent for CO$_2$ hydrogenation reaction was degased and stored under argon before reaction.

2.4.2 Synthesis and characterization of ligands and complexes

The preparation and characterization of ligands **L1-L4, L6, L10** and complexes **1-4, 6 and 10** can be found in previous work.$^{[116]}$ Details about ligand **L7** and complex 7 can be found in Jennifer Smith’s thesis from the Xiao group and the characterization of 7 is quoted in this section for comparison.

Ligand **L5** was prepared according to literature procedures.$^{[147]}$
**L5**: white solid; $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ (ppm) = 8.05 (d, $J = 7.9$ Hz, 2H), 7.71 (d, $J = 7.9$ Hz, 2H), 7.33 (m, 10H), 5.50 (s, 1H), 4.94 (s, 2H); $^{13}$C$\{^1$H$\}$ NMR (100 MHz, CDCl$_3$) $\delta$ (ppm) = 161.99, 143.18, 133.60, 132.92 (q, $J_{C\text{-}F} = 32.4$ Hz), 128.95, 127.95, 127.86, 126.73, 125.72 (q, $J_{C\text{-}F} = 4.0$ Hz), 123.95 (q, $J_{C\text{-}F} = 270.7$ Hz), 29.85; $^{19}$F$\{^{13}$C$\}$ NMR (376 MHz, CDCl$_3$) $\delta$ (ppm) = -62.84; $m/z$ (ESI$^+$) 367.1 [M+H]$^+$.  

Ligands **L8** and **L9** were prepared according to literature procedures.$^{[147-149]}$

**L8**: white solid; $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ (ppm) = 7.87 (d, $J = 12.0$ Hz, 2H), 7.30 (m, 10H), 6.97 (d, $J = 12.0$ Hz, 2H), 4.87 (s, 2H), 4.20 (t, $J = 4.0$ Hz, 2H), 3.89 (t, $J = 4.0$ Hz, 2H), 3.75-3.73 (m, 2H), 3.61-3.58 (m, 2H), 3.40 (s, 3H); $^{13}$C$\{^1$H$\}$ NMR (100 MHz, CDCl$_3$) $\delta$ (ppm) = 162.83, 161.19, 143.62, 129.10, 128.79, 127.59, 126.72, 122.61, 114.64, 72.05, 70.93, 69.76, 67.66, 59.20, one resonance was not observed; $m/z$ (ESI$^+$) 417.2 [M+H]$^+$.  

**L9**: white solid; $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ (ppm) = 7.88 (d, $J = 8.0$ Hz, 2H), 7.37-7.26 (m, 10H), 6.95 (d, $J = 8.0$ Hz, 2H), 5.40 (b, 1H), 4.88 (s, 2H), 4.01 (t, $J = 4.0$ Hz, 2H), 1.81 (m, 2H), 1.48 (m, 2H), 1.27 (overlap, 28H), 0.89 (t, $J = 4$ Hz,
$^3$H; $^{13}$C{$_1^H$} NMR (100 MHz, CDCl$_3$) δ(ppm) 162.85, 161.54, 143.77, 131.09, 129.04, 128.77, 127.55, 126.73, 122.35, 114.50, 68.29, 32.02, 29.80, 29.76, 29.70, 29.68, 29.49, 29.46, 29.28, some resonance were not observed due to overlap, 26.11, 22.79, 14.22; $m/z$ (ESI$^+$) 567.4 [M+H]$^+$. 

Complex 5, 8 and 9 were prepared using the method of Davies et al.$^{[150]}$ and experimental details can be found in previous publication.$^{[116]}$ Iridium complexes X were synthesized from the corresponding ligands LX. Particularly, complexes 5, 8 and 9 all consist of two inseparable regioisomers 5a/5b, 8a/8b and 9a/9b resulting from the competing cyclometallation of the C$_2$ and C$_4$ phenyl rings in the NaOAc-mediated cyclometallation reaction.

Complex 5 (R = CF$_3$): 5a:5b = 1.5:1, yellow powder; 0.10 mmol scale, yield 59 mg, 86%; column: DCM/methanol=10:1 (several drops of ammonia); $^1$H NMR (400 MHz, CDCl$_3$) δ (ppm) = 8.09 (s, 0.4H), 8.01 (s, 0.6H), 7.48–7.20 (m, overlapped, 10H), 7.21 (m, 1.4H), 7.11 (d, $J$ = 7.9 Hz, 0.6H), 6.25 (s, 0.6H), 5.62 (s, 0.4H), 5.16 (d, $J$ = 5.8 Hz, 0.4H), 4.96 (d, $J$ = 11.5 Hz, 0.6H), 4.86 (d, $J$ = 11.6 Hz, 0.6H), 4.76 (d, $J$ = 5.8 Hz, 0.4H), 1.45 (s, 6H), 1.43 (s, 9H). $^{13}$C{$_1^H$} NMR (100 MHz, CDCl$_3$) δ (ppm) = 176.79, 175.79, 164.95, 164.71, 143.16, 141.62, 139.81, 139.07, 137.64, 132.50 (q, $J$ = 4.0 Hz), 131.97 (q, $J$ = 3.7 Hz), 129.14, 129.10, 128.91, 128.82, 128.75, 128.56, 128.41, 128.37, 127.84, 127.42, 127.31 124.72, 124.68, 118.68 (q, $J$ = 4.0 Hz), 118.48 (q, $J$ = 4.0 Hz), 88.41, 87.80, 79.75, 79.62,
Chapter 2

72.44, 72.08, 9.39, 9.14; $^{19}$F-$^{13}$C NMR (376 MHz, CDCl$_3$) $\delta$ (ppm) = -62.22; $m/z$ (ESI$^+$) 693.2 [M-Cl]$^+$.  

**Complex 8 (R = -O(CH$_2$CH$_2$O)$_2$CH$_3$):** 8a:8b = 1.5:1; yellow powder; 0.12 mmol scale, yield 88 mg, 90%; column: DCM/methanol=10:1 (several drops of ammonia); $^1$H NMR (400 MHz, CDCl$_3$) $\delta$ (ppm) = 7.53-7.22 (m, overlapped, 15H), 6.62 (dd, $J = 8.0$, 4.0 Hz, 0.4H), 6.55 (dd, $J = 8.0$, 4.0 Hz, 0.6H), 5.63 (s, 0.6H), 5.32 (d, $J = 12.0$ Hz, 0.7H), 5.12 (d, $J = 4.0$ Hz, 0.4H), 4.98 (d, $J = 12.0$ Hz, 0.7H), 4.78 (d, $J = 12.0$ Hz, 0.7H), 4.68 (d, $J = 4.0$ Hz, 0.4H), 4.31-4.17 (m, 2H), 3.90 (q, $J = 4.0$ Hz, 2H), 3.76 (m, 2H), 3.61 (m, 2H), 3.42 (s, 3H), 1.45 (s, 15H); $^{13}$C-$^1$H NMR (100 MHz, CDCl$_3$) $\delta$(ppm) = 176.76, 176.15, 167.54, 166.68, 161.62, 161.06, 143.90, 142.12, 140.16, 139.45, 129.04, 128.97, 128.83, 128.52, 128.40, 128.13, 127.67, 127.46, 127.39, 126.07, 126.02, 121.06, 120.83, 109.09, 108.66, 87.84, 87.26, 79.38, 77.30, 72.45, 72.07, 70.85, 70.00, 67.18, 67.11, 59.18, 9.50, 9.25; $m/z$ (ESI$^+$) 743.3 [M-Cl]$^+$; Crystals suitable for XRD analysis were obtained from DCM/Et$_2$O.

2.2.3 General procedure for CO$_2$ hydrogenation

A stock solution of a complex 1-10 was freshly made by dissolving a certain amount of the complex in dry DCM (0.4 mM). Under argon flow, the catalyst stock solution was added into a 100 or 300 mL autoclave and DCM volatilized to dry. KOH solid was then added into the autoclave followed by the degased solvent.
The autoclave was tightened afterwards and purged three times with CO\textsubscript{2} before it was pressurized with CO\textsubscript{2} and then H\textsubscript{2} to get a certain pressure at room temperature. The reaction mixture was stirred at certain temperature for 0.5 - 20 h before it was cooled down with an ice-water bath. The determination of product amount was achieved with $^1$H NMR or ion chromatograph:

(1) $^1$H NMR method: The reaction mixture solution was dried under vacuum. 5 mL of 0.1 M sodium $p$-toluenesulfonate aqueous solution was added to dissolve the white solid. 0.1 mL of the mixture solution and 0.4 mL of D\textsubscript{2}O were mixed together in a NMR tube and then submitted to get the $^1$H NMR spectrum (e.g. Appendix, Scheme A.1).

(2) Ion chromatograph method: The reaction mixture was diluted and then submitted to the ion chromatograph to determine the product amount (after calibration).

2.2.4 Contact angle measurement

Complex 8 and 9 powder was thoroughly dried under vacuum. Catalyst film (1 cm in diameter on mica sheet) for contact angle measurement was made using tablet machine. The film was blown with rubber suction bulb to obtain a flat surface proper for water contact measurement.
Chapter 3 Hydrogenation of CO$_2$ to FA Catalyzed by Ir-$N,N'$ Diimine Catalysts
3.1 Introduction

Catalytic hydrogenation of CO₂ to chemicals and fuels is an ideal way to reduce the atmospheric CO₂ concentration and fix CO₂ as a C₁ resource, provided that hydrogen is produced from renewable resources.[18,151-154] Chapter 1 reviews homogeneous hydrogenation of CO₂ to FA/formate with molecular catalysts in a wide variety of organic solvents, ionic liquids, water and supercritical CO₂, usually in the presence of a base affording formate as the product (eqn. 3.1), which is the case we discussed in the last chapter.

\[
\text{CO}_2 + \text{H}_2 \xrightarrow{\text{Catalyst}} \text{HCOOH} \xrightarrow{\text{NaOH}} \text{HCOONa} \tag{3.1}
\]

In most of the currently reported catalyst systems, base is needed to enhance the hydrogenation of CO₂ to formate. Nevertheless, from the viewpoint of atom economy and eco-friendly process, the direct hydrogenation of CO₂ to FA in water without consuming stoichiometric amount of base is highly appreciated and of great significance. However, the development of novel catalysts for efficient hydrogenation of CO₂ in water without adding base remains challenging. Based on the reported half-sandwich iridium catalysts with bipyridine-derived ligands and the results obtained with the cyclometallated Ir-N=C complexes (last chapter), this chapter will focus on the design of [IrCp*L] catalyst for the base-free aqueous hydrogenation of CO₂ to FA.

Several key challenges associated with this transformation were anticipated. First, the ideal catalyst should be active toward C=O double bond hydrogenation. Second, the catalyst should be soluble in aqueous solution. Third, CO₂-saturated water shows pH 4.0 at 20 °C;[155] thus the catalyst must be stable under acidic conditions. Based on these considerations, this chapter mainly explores iridium complexes containing nonaromatic N,N’-diimine ligands.[156-159] Although they
haven’t been applied for CO₂ hydrogenation, these imidazoline analogues are potentially active towards this transformation in view of its good water solubility, coordination ability and electron-donating property.\textsuperscript{[160, 161]}

3.2 Hydrogenation of CO₂ to FA with Ir-\textit{N,N’} Complex in Water

3.2.1 Ir-catalyzed CO₂ hydrogenation in water without base

The study started from identifying homogeneous iridium catalysts capable of hydrogenating CO₂ to FA in water without base. A series of N,N’ ligands, \textbf{L11-L20}, were screened in combination with [IrCp*Cl₂]₂ for the hydrogenation of CO₂ and the results are listed in Table 3.1. FA was the only product detected by \textsuperscript{1}H NMR (Appendix, Scheme B.1).

Through lowering the conjugacy level of the coordinating N atom and introducing hydrophilic group, i.e. the NH unit, the electron-donating ability and hydrophilicity both increase from \textbf{L11} to \textbf{L18}. Clearly, the TOF value increases dramatically from none (Table 3.1, entry 1, 2) to near 1000 h\textsuperscript{-1} (Table 3.1, entries 7, 8). Noteworthy is that ligands \textbf{L14-L16}, which contain less electron-donating pyridine and are less water-soluble, show much lower activity than the analogues \textbf{L17-L18}. These results demonstrate that the half sandwich iridium catalysts with non-aromatic \textit{N,N’}-diimine ligand are superior for CO₂ hydrogenation to FA compared with iridium complexes bearing aromatic pyridine-type ligands under the given reaction conditions. The two structure analogues \textbf{L17} and \textbf{L18} present similar high TOFs of 1000 h\textsuperscript{-1} and 928 h\textsuperscript{-1}, respectively. Replacing the NH motif of \textbf{L17} with O, i.e. ligand \textbf{L19}, gives a lower TOF of 320 h\textsuperscript{-1} for FA production (Table 3.1, entry 9). The \textit{in situ} formed iridium catalyst with the tetrahydroxy-bipyrimidine ligand \textbf{L20} reported by Himeda and Fujita et al. gives a TOF of only 80 h\textsuperscript{-1} under such reaction conditions (Table 3.1, entry 10).

General reaction conditions: [IrCp*Cl\(_2\)]_2 (0.125 μmol), Ir/L = 1/1.2, H\(_2\)O (10.0 mL), CO\(_2\)/H\(_2\) = 1/1 (5.0 MPa), at 40 °C, 30 min; \(^a\) average values from two runs with an error less than 10%; \(^b\) Complex 11 as the catalyst (0.25 μmol); \(^c\) Complex 12 as the catalyst (0.25 μmol). No reac...
tion was detected without catalyst.

![Scheme 3.1 Synthesis and X-Ray structures of complex 11 and 12](image)

L17 and L18 can be viewed as conjugated N,N’-diimine ligands (non-aromatic ligands), essentially different from the aromatic bipyridine, bipyrimidine and bimidazole ligands, and have never been used for the hydrogenation of CO₂.[162]

Well-defined complex 11 and 12 were subsequently synthesized in high yields from [IrCp*Cl₂]₂ and ligand L17 and L18, respectively (Scheme 3.1). These two complexes are air-stable and water-soluble, and their crystal structures were determined by X-ray diffraction. For both complexes in the solid state, the iridium atom bonds to the Cp* ligand, a chloride ligand and the two nitrogen atoms of the N,N’-ligand, forming a distorted octahedral coordination geometry with a chloride anion situated outside. The only difference is that complex 11 contains two water molecules, while complex 12 contains none.

With complexes 11 and 12 as the catalyst, TOFs of 1024 h⁻¹ and 952 h⁻¹ were achieved for the CO₂ hydrogenation. These are almost the same level as that of the
catalysts formed \textit{in situ} (Table 3.1, entries 7 vs. 11, 8 vs. 12), indicating that both the prepared iridium complex and the \textit{in situ} formed catalyst can transform into the active species rapidly under the given reaction conditions. Based on a series of exploration, complex 12 was used as the catalyst in the following studies due to its excellent stability.

3.2.2 Reaction Mechanism Study

The complex 12 catalyzed hydrogenation of CO\textsubscript{2} was then investigated under varied reaction conditions to gain mechanistic insight. Firstly, the reaction rate increases with elevating of temperature, and a high TOF of 13104 h\textsuperscript{-1} was obtained at 80 °C for FA production under 5.0 MPa of CO\textsubscript{2}/H\textsubscript{2} (1/1) in water (Table 3.2). The apparent activation energy (E\textsubscript{a}) is estimated to be 44 kJ\textbullet}mol\textsuperscript{-1} (Scheme 3.2), showing that this catalyst is intrinsically active for the hydrogenation of CO\textsubscript{2}.

\textsuperscript{a} Reaction conditions: complex 12 as the catalyst (0.25 μmol), H\textsubscript{2}O (50.0 mL), CO\textsubscript{2}/H\textsubscript{2} = 1/1 (5.0 MPa). \textsuperscript{b} Averaged value from two runs with an error less than 10%; \textsuperscript{c} TOF calculated based on the indicated reaction time.
Scheme 3.2 Arrhenius plot of initial TOF values for hydrogenation of CO$_2$ using complex 12

The effect of the catalyst concentration on the reaction rate was also investigated and the double logarithmic plot of the initial rate against the catalyst concentration shows linear dependence (Scheme 3.3), revealing approximately a pseudo-first order (0.75) in the concentration of catalyst precursor.

Scheme 3.3 Plot of Ln (rate) versus Ln([12]): complex 12 as the catalyst (0.1-5.0 μmol), H$_2$O (50.0 mL), 5.0 MPa of CO$_2$/H$_2$ (1/1), 40 °C, 15 min, conversion less than 10%.
As shown in Scheme 3.4, the partial pressures of H₂ and CO₂ both affect the rate of CO₂ hydrogenation. When CO₂ pressure was maintained at 4.0 MPa, the H₂ pressure-dependent FA production increases with the increasing pressure of H₂ to approach a constant value (●). The CO₂ pressure-dependent FA production with H₂ pressure maintained at 4.0 MPa shows a similar trend and also exhibits saturation behavior (■). The hydrogenation activity with complex 12 linearly depends on P_{H₂} and P_{CO₂} at P_{H₂} and P_{CO₂} < 4.0 MPa; thus it can be concluded that this reaction show first order dependence with respect to both substrates under the given conditions. These results appear to indicate that the turnover rate of the hydrogenation is determined by the step of CO₂ insertion into an iridium-hydride bond (vide infra).

A deuterium kinetic isotope effect (KIE) study was then conducted for the CO₂ hydrogenation. As shown in Table 3.3, when the solvent H₂O was replaced with D₂O, the reaction rate increased remarkably either using H₂ where the TOF increased from 280 h⁻¹ in H₂O to 768 h⁻¹ in D₂O (Table 3.3, entries 1 vs. 3) or using...
D$_2$ with which the TOF increased from 272 h$^{-1}$ in H$_2$O to 548 h$^{-1}$ in D$_2$O (Table 3.3, entries 2 vs. 4). Inverse solvent isotope effect (SIE) of 0.36 and 0.48 was obtained from the reactions with H$_2$/D$_2$O and D$_2$/D$_2$O, respectively, which is also confirmed with $^1$H NMR (Appendix, Scheme B.2), illustrating D$_2$O as solvent being more favorable for the CO$_2$ hydrogenation than H$_2$O. In addition, the results in Table 3.3 also indicate that in H$_2$O, the reaction rate decreased slightly by replacing H$_2$ with D$_2$ (Table 3.3, entries 1 vs. 2), and replacing H$_2$ with D$_2$ in D$_2$O also decreased the reaction rate (Table 3.3, entries 3 vs. 4).

$^a$ General reaction conditions: complex 12 (0.25 μmol), H$_2$O or D$_2$O (10.0 mL), CO$_2$/H$_2$ or CO$_2$/D$_2$ = 1/1 (2.0 MPa); at 40 °C, 30 min; $^b$ Average values from two runs with an error less than 10%. $^c$ KIE = TOF (entry 1)/TOF (entry n) (n = 2, 3, 4)

As mentioned in the last chapter, water effect in homogeneous hydrogenation of CO$_2$ has been widely noted and investigated. For instance, in organic solvents, small amount of added water can enhance the reaction rates presumably by stabilizing the transition state through an H-bonding interaction between the coordinated water molecule and the oxygen atom of the approaching CO$_2$ in its insertion to a metal-hydride bond.$^{[72]}$ Moreover, in basic aqueous solution, a normal KIE was obtained with a proton-responsive iridium complex for CO$_2$ hydrogenation to formate,$^{[69]}$ demonstrating the involvement of water in the rate-determining step to accelerate the heterolysis of H$_2$. In our case, the significant inverse KIE results
imply that water might play an additional role.\textsuperscript{[163]}

\textsuperscript{a} General reaction conditions: Cat. (0.25 μmol), H\textsubscript{2}O (10.0 mL), CO\textsubscript{2}/H\textsubscript{2} = 1/1 (5.0 MPa), at 40 °C, 30 min; \textsuperscript{b} Measured on SHINEHA CIC-100 ion chromatograph with the Shodex column (IC SI-52 4E); \textsuperscript{c} Averaged rate for initial 30 min. \textsuperscript{d} Reaction solution: H\textsubscript{2}O (9.5 mL) + MeOH (0.5 ml).  

Inverse KIE (KIE<1) resulting from a SIE is a signature for pre-equilibrium aquo release from a metal center, which has been well documented in the literature.\textsuperscript{[164, 165]} It has been reported that many of the half-sandwich cyclopentadienyl [IrCp*(L)Cl] complexes hydrolyze in water to form [IrCp*(L)(H\textsubscript{2}O)] complexes which are generally considered as the precursors of the active species.\textsuperscript{[166, 167]} In this context, the aquo iridium complex [Cp*Ir(L\textbf{18})(H\textsubscript{2}O)][BF\textsubscript{4}]\textsubscript{2} (complex \textbf{13}) was synthesized and applied to the CO\textsubscript{2} hydrogenation, and a TOF of 1000 h\textsuperscript{-1} for the production of FA was obtained, almost the same level as complex \textbf{12} (Table
3.4, entries 1 vs. 2). Thus when used for the hydrogenation of CO₂ in water, complex 12 is proposed to hydrolyze first to form the aqua complex. Afterwards, an equilibrium process involving the dissociation of the coordinating water molecule from the iridium center occurs, which precedes the turnover-limiting step. Due to the easier dissociation of D₂O from the iridium center than H₂O or more favorable equilibrium of D₂O dissociation than H₂O (eqn. 3.2 & 3.3),¹⁶⁵ the reaction rate in D₂O is expected to be faster, giving rise to the observed inverse KIE. Therefore, the aquo iridium species formed from complex 12 in water is considered to be an active species and water release from the iridium center could be an important process that affects the rate of this reaction.

\[
\begin{align*}
[\text{Ir-OH}_2]^{2+} + H_2O & \rightleftharpoons K_H \quad [\text{Ir}]^{3+} + H_2O\cdots H_2O \\
[\text{Ir-OD}_2]^{2+} + D_2O & \rightleftharpoons K_D \quad [\text{Ir}]^{3+} + D_2O\cdots D_2O
\end{align*}
\]

(3.2)

(3.3)

It was also found that the addition of other coordinating ligands retarded this reaction, likely by diminishing the concentration of active species. For example, the FA production with complex 12 declines with the increasing amount of NaCl added in (Table 3.4, entries 3-6). With the addition of NaI, the rate drop was more significant (Table 3.4, entries 7-9). When PPh₃ was added to the hydrogenation reaction with complex 13 as the catalyst (Table 3.4, entry 10), no reaction was observed, probably because the strong coordination ability of PPh₃ leads to its difficult dissociation from iridium center, blocking the coordination of H₂.¹⁶⁸ These results support indirectly the notion that water dissociation from the iridium center is a precondition for catalysis to occur.

The possible catalytic intermediates generated from complex 12 were monitored by ¹H NMR. When H₂ (1.5 Mpa, 25 °C) was filled to the H₂O/CD₃OD solution of 12, a new peak at δ = -12.09 ppm (Appendix, Scheme B.4) appeared immediately, which can be assigned to the chemical shift of a [Ir-H]⁺ species.⁶²,⁶⁷
Switching to a H$_2$/CO$_2$ mixture (1.2 MPa), besides the peak of the [Ir-H]$^+$ species, another new peak at $\delta = 8.19$ ppm appeared, which is assigned to the chemical shift of H-CO$_2$H (Appendix, Scheme B.5). In H$_2$O/D$_2$O solution, although FA could be detected ($\delta = 8.30$ ppm, Appendix, Scheme B.6), the iridium hydride was not observed even for a long time under H$_2$/CO$_2$ pressure, possibly due to the instability of this iridium hydride in the more acidic water solution compared to the H$_2$O/CD$_3$OD solution. It is important to note that during the in-situ $^1$H NMR probing, the iridium complex (likely [12-H$_2$O]$^{2+}$) remained as it was from the beginning. These observations indicate the aqua complex to be the catalyst resting state.

**Scheme 3.5** Proposed mechanism for base-free aqueous CO$_2$ hydrogenation with complex 12

Based on these results, the catalytic cycle of the aqueous hydrogenation of CO$_2$ with complex 12 under acidic conditions is proposed in Scheme 3.5. Firstly, com-
plex 12 hydrolyzes rapidly in water, forming the aquo complex A. Then the catalytic cycle experiences the H$_2$-coordinated iridium species B (step I), the iridium hydride species C (step II) and the iridium formato species D (step III) in sequence, corresponding to the H$_2$ coordination step, H$_2$ splitting process and CO$_2$ insertion process, respectively. Each of these reactions is reversible, as will be presented in the next chapter. During the catalytic reaction, the iridium formato complex D is undetectable with $^1$H NMR either in water or in H$_2$O/CD$_3$OD mixture (Appendix, Scheme B.5, B.6), suggesting the rapid exchange of the formate with a hydronium ion (H$_3$O$^+$) to produce HCO$_2$H (step IV, $\delta = 8.30$ ppm in H$_2$O/D$_2$O, Appendix, Scheme B.6; $\delta = 8.19$ ppm in H$_2$O/CD$_3$OD, Appendix, Scheme B.5) and the regeneration of iridium aqua complex A.

The linear dependence of the reaction rate on the pressure of H$_2$ and CO$_2$ appears to suggest that the hydrogenation is turnover-limited by the step of CO$_2$ insertion under the conditions employed, which is also supported by the detection of a [Ir-H] species and the invisibility of the iridium formato species during $^1$H NMR monitoring of the reaction.

### 3.2.3 Thermodynamics of the base-free aqueous hydrogenation of CO$_2$

Apart from the kinetic study, the thermodynamics of the CO$_2$ hydrogenation to FA catalyzed by complex 12 was also investigated. Scheme 3.6 shows the time-dependent TONs at 40 $^\circ$C under 5.0 MPa of CO$_2$/H$_2$. A TOF of 2174 h$^{-1}$ was achieved in the first fifteen minutes. The FA amount obtained after 17 h reached a constant value, implying that the equilibrium shown in eqn. 3.1 has been reached.
Scheme 3.6 Plot of FA amount versus the reaction time

Reaction conditions: complex 12 (0.25 μmol), H₂O (50.0 mL), 40 °C, 5.0 MPa CO₂/H₂ (1/1).

Scheme 3.7a shows that the final TON increases with decreasing temperature, though the initial reaction rate increases with the increasing reaction temperature (Table 3.2). This agrees well with the reaction being exothermic. For long-time reaction, increasing the total pressure of H₂/CO₂ greatly increases the final TON (Scheme 3.7b), which shifts the reversible reaction forward (eqn. 3.1). Thus, naturally a high TON of 10258 was achieved at a low temperature of 40 °C and high pressure of 7.6 MPa of H₂/CO₂ (1:1).
Scheme 3.7 (a) TON of CO$_2$ hydrogenation at different temperatures; (b) TON of CO$_2$ hydrogenation under varied total gas pressure.

General conditions: complex 12 (0.25 μmol), H$_2$O (50.0 mL), 40 °C, CO$_2$/H$_2$ = 1/1, 8-90 h.

3.3 Hydrogenation of CO$_2$ to Formate with Ir-N,N’ Complex

The hydrogenation of CO$_2$ to formate in the presence of base was also investigated with complex 12. As shown in Table 3.5, the hydrogenation reaction proceeds faster. A TOF of 37488 h$^{-1}$ was obtained at 80 °C and 5.0 MPa of CO$_2$/H$_2$ (1:1) in 50 mL of 1 M NaHCO$_3$ aqueous solution (Table 3.5, entry 1), which is comparable with the best literature results under similar reaction conditions in water.$^{[66]}$ A TON of 87200 was achieved when the reaction was carried out in 1 M of NaHCO$_3$ solution after 16 hours (Table 3.5, entry 2). When more soluble KHCO$_3$ was used as the base, a solution of 0.98 M potassium formate was yielded with a TON of 196800 in 24 h (Table 3.5, entry 3). As mentioned earlier, complex 11 is less stable than 12. For the long-time hydrogenation of CO$_2$ in basic solution, complex 11 gave a TON of 53200 in 24 h, which is much less compared with complex 12 (Table 3.5, entry 4). Thus the following studies were performed with 12 as well.

Table 3.5 Results of the hydrogenation reaction in the presence of base$^a$

\textsuperscript{a} General conditions: complex 12 (0.25 μmol), NaHCO\textsubscript{3} (1M, 51 mL), CO\textsubscript{2}/H\textsubscript{2} = 1/1 (5.0 MPa), 1h; \textsuperscript{b} reaction time is 5 min.

The apparent activation energy (E\textsubscript{a}) of 47 kJ\textsuperscript{-}mol\textsuperscript{-1} was obtained from the temperature dependence of the initial reaction rate in aqueous NaHCO\textsubscript{3} solution (Table 3.6, Scheme 3.8), almost the same as that (44 kJ\textsuperscript{-}mol\textsuperscript{-1}) obtained in water without base.

In the presence of base, KIE study was also performed. As shown in Table 3.7, when the hydrogenation of CO\textsubscript{2} was carried out in H\textsubscript{2}O using NaHCO\textsubscript{3} as the base, a TOF of 2728 h\textsuperscript{-1} and 2824 h\textsuperscript{-1} was obtained with H\textsubscript{2} and D\textsubscript{2}, respectively (Table 3.7, entries 1, 2). The KIE value of 0.97 indicates that H\textsubscript{2} heterolysis may not be the rate-determining step. When the reaction was carried out in D\textsubscript{2}O (NaDCO\textsubscript{3} as base), the reaction rate decreased slightly, and a KIE of 1.12 and 1.24 was ob-

tained with H$_2$ and D$_2$ (Table 3.7, entries 3, 4). Compared with the KIE results in the absence of base, the KIE in the presence of base is not that significant. Worth noting is that a reverse KIE is not observed suggesting that water dissociation no longer affects the hydrogenation rate. The slightly higher KIE shown in entry 4 may indicate that CO$_2$ insertion into the Ir-H bond is rate limiting.

$^a$ Reaction conditions: complex 12 as the catalyst (0.25 μmol), NaHCO$_3$/H$_2$O or NaDCO$_3$/D$_2$O (1.0 M, 10.0 mL), CO$_2$/H$_2$ = 1/1 (2.0 MPa); 40 °C, 30 min. $^b$ Average values from two runs with an error less than 10%.

The behavior of complex 12 in water under different pH conditions was studied using UV-Vis absorption spectroscopy. As shown in Scheme 3.9, the complex re-
mains unchanged structurally below pH 6, and loses the NH proton on the ligand under basic conditions.\textsuperscript{[68, 128, 169]} The pKa value of complex 12 in water was estimated to be 8.2. \textsuperscript{1}H NMR of complex 12 in H\textsubscript{2}O/D\textsubscript{2}O and CDCl\textsubscript{3} both manifest the disappearance of the NH proton after the addition of Na\textsubscript{2}CO\textsubscript{3} and NaOtBu (Appendix, Scheme B.7, B.8).

\begin{figure}
\centering
\includegraphics[width=\textwidth]{Scheme39.png}
\caption{(a) The UV-Vis absorption spectra of complex 12 measured at pH values in the range from 2.0 to 12.0; (b) Absorbance changes at 255 nm, 279 nm, 316 nm and 389 nm as a function of pH change.}
\end{figure}

Based on these investigations and the \textit{in situ} \textsuperscript{1}H NMR results, the reaction mechanism of CO\textsubscript{2} hydrogenation to formate in the presence of base with com-
plex 12 is tentatively proposed in Scheme 3.10.

![Scheme 3.10 Proposed mechanism for CO₂ hydrogenation in the presence of base](image)

As mentioned above, complex 12 will lose the NH protons in basic solution. Deprotonation of the NH unit likely results in a ligand isomerization and the resulting electron-donating amide may expell the coordinating aquo ligand, forming the electro-neutral complex A' as shown in Scheme 3.10. This would explain why there is no SIE. When the hydrogenation of CO₂ was performed using complex 12 in NaOH/H₂O/D₂O solution which was bubbled with continuous flow of H₂/CO₂ (1:1) for 10 min, the intermediate iridium hydride (potentially B') was detected at δ = -11.91 ppm by ¹H NMR (Appendix, Scheme B.9). Additionally, a signal of 8.37 ppm was observed, which is ascribed to the free formate proton (HCOO⁻) dissociated from the Ir-formato complex C'. Since the formato proton signal of C' was not detected, CO₂ insertion is again proposed to be the RDS, which is in line with the KIE results, and the similarity in the Ea’s obtained for the base-free and
base-promoted reactions. Nevertheless, further study still need to be done in the future to understand more about the reaction mechanism.

3.4 Summary

An efficient iridium complex has been developed for the direct hydrogenation of CO₂ to FA in water without base under mild conditions. A TOF over 13000 h⁻¹ was obtained at 80 °C and 5.0 MPa, which is the highest TOF reported to date under similar conditions.

The in situ ¹H NMR and kinetic isotopic effect study reveals that whilst the CO₂ insertion may be the rate-limiting step, the dissociation of the coordinated water molecule from the iridium complex affects considerably the turnover rate of the catalytic cycle. Thus, water appears to play a double role in this reaction, facilitating CO₂ insertion via hydrogen bonding, and limiting the catalytic turnover through coordination to the active catalytic center.

The successful application of the iridium N,N'-diimine complex for base-free CO₂ hydrogenation extends the ligand type and provides a strategy to develop new catalytic systems for CO₂ hydrogenation. Moreover, this iridium catalyst also shows satisfying reactivity for the hydrogenation of CO₂ in basic aqueous solution, making it more adaptable to various potential applications in the future.

3.5 Experimental Section

3.5.1 General information

**Instruments:** Details have been given in Chapter 2. Solution pH was measured on a ZDJ-400DH multi-function titrator which was calibrated before use. The X-Ray structures of complexes 11-13 were determined by State Key Laboratory of Organometallic Chemistry (Shanghai).
**Chemicals:** NaHCO₃, Na₂CO₃, KOH, and KHCO₃ were purchased from Tianjin Kemiou Chemical Reagent Co., Ltd. Sodium formate was purchased from Sinopharm Chemical Reagent Co. Ltd. [IrCp*Cl₂]₂, ligand L₁₁ and L₁₉ were purchased from J&K. 3-(Trimethylsilyl)-1-propane sulfonic acid sodium salt (DSS) was purchased from Aladdin. Deionized water used in this work was obtained from PURELAB Ultra water purification system. Other ligands were synthesized according to literature procedures.

### 3.5.2 Synthesis and characterization of ligands and complexes

Complex 11 [IrCp*($^1$L17)Cl]Cl:

Under an argon atmosphere, dry methanol (30 mL) was added to the mixture of [IrCp*Cl]$_2$ (0.1 mmol) and L17 (0.2 mmol) in a flask bottle which was stirred at room temperature. After approximately half an hour, the mixture became a yellow-green clear solution, and stirring was maintained overnight. Then, the methanol was removed under reduced pressure. Diethyl ether was added to the residue, which created a powder. After being filtered and washed with ether, a yellow powder was obtained. If the powder could not be formed after adding ether, column chromatography was used to purify the complex using CH$_2$Cl$_2$/MeOH (50:1-20:1) as the eluent. Yield: 84%. Crystal of complex 11 that was suitable for X-ray diffraction was obtained from a mixture of CH$_2$Cl$_2$ and ether. $^1$H NMR (400 MHz, D$_2$O): $\delta$ (ppm) = 3.88-3.99 (m, 8H), 1.67 (s, 15H); $^{13}$C $^1$H NMR (100 MHz, D$_2$O): $\delta$ (ppm) = 161.4, 87.8, 51.8, 46.7, 8.6; m/z (ESI$^+$) 501.1 [M-Cl]$^+$; elemental analysis for C$_{16}$H$_{25}$Cl$_2$IrN$_4$•H$_2$O calcd: C 34.66, H 4.91, N 10.10; found:
C 35.02, H 5.23, N 9.81.

C₁₆H₂₉Cl₂Ir₄O₂, CH₂Cl₂/Et₂O, \( M = 572.53 \), yellow crystals, 0.145 x 0.111 x 0.066 mm³ Monoclinic, Space group \( P \ 21/c \), \( a = 7.6158 \ (8) \ \AA, \ a = 90°, \ b =11.7394(12) \ \AA, \ \beta = 97.916(2)°, \ c = 23.093(2) \ \AA, \ \gamma = 90°, \ V = 2044.9(4) \ \AA^3, \ Z = 4, \ D_c = 1.860 \text{ mg/m}^3, \ T = 293 (2) \text{ K}, 11740 \text{ reflections collected, 4020 independent reflections} \ R_{int} = 0.0340, \text{ Goodness-of-fit on } F^2 = 1.121, R1 = 0.0317, wR2 = 0.0681, 6 restraints, 255 parameters, absorption coefficient = 6.807 \text{ mm}^{-1}.

3.5.3 Procedure for catalytic hydrogenation of CO$_2$ in water

The *in situ* prepared catalysts were freshly formed from [IrCp*Cl$_2$]$_2$ (1.0 equiv.) and ligands (2.4 equiv.) in degassed water with the help of ultrasonic wave. The catalyst stock solution was kept for the hydrogenation reaction within 10 h. Similarly, the stock solution of complex 11, 12 and 13 were prepared using degassed water.

For the hydrogenation reaction without base, degassed water (9.0 mL) and the catalyst stock solution (1.0 mL) were added to a 300 mL glass-lined stainless steel autoclave reactor equipped with a stirring bar under argon protection. The autoclave was then sealed, purged three times with CO$_2$ carefully and finally pressurized to the required pressure. Then hydrogen was filled till the total pressure reached the desired value. The autoclave reactor was stirred in a water bath right away with temperature held at the desired value in advance. After the reaction, e.g. 30 min, the autoclave was put into an ice-water bath and gas was slowly released in a fume hood upon cooling. Afterwards, NaOH (1.0 M, 0.5 mL) was added to the reaction solution which was then diluted with water and submitted to SHINEHA CIC-100 ion chromatograph to determine the amount of formate generated.

For long-time reaction, the CO$_2$ hydrogenation reaction was performed directly
in the autoclave without glass lining to avoid the influence of solvent evaporation. The blank reaction was carried out without catalyst at 40 °C and 5.0 MPa of CO₂/H₂ (1/1) for 16 h, and only trace amount of FA was detected, which is negligible.

For the hydrogenation reaction in the presence of base, the procedure was exactly the same as described above, using basic aqueous solution (1 M NaHCO₃ or 2 M KHCO₃) instead of water.

3.5.4 UV-Vis absorption measurement

The pH of the solutions was adjusted by mixing the stock solution of complex 12 (0.15 mM) in 0.02 M H₂SO₄ and 0.1 M NaOH. The UV/Vis spectra were recorded right after testing the pH value.
Chapter 4 Formic Acid Dehydrogenation Catalyzed by Ir-\(N,N'\) diimine Catalysts
4.1 Introduction

Formic acid is a promising chemical hydrogen storage compound because it is a nontoxic liquid at ambient temperature and can be easily handled and transported.\[176-179] The dehydrogenation of FA (eqn. 4.1), as a companion reaction to CO\(_2\) hydrogenation, is an indispensable step in a hydrogen storage system using FA as the hydrogen storage material. The hydrogenation of CO\(_2\) to formate/FA under mild conditions has been discussed in Chapters 2 and 3; thus this chapter will focus on the dehydrogenation of FA using homogeneous catalysts.

\[
\text{HCOOH} \quad \text{Catalyst} \quad \text{CO}_2 + \text{H}_2 \quad (4.1)
\]

The dehydrogenation of FA to generate hydrogen has been extensively studied in the past few years. Homogeneous catalysts based on ruthenium,\[32, 109, 110, 113, 122, 129, 180-182\] rhodium,\[70, 124, 128\] iridium,\[53, 66-68, 116, 120\] iron\[114, 117, 118, 183, 184\] and other complexes\[115, 138\] have been widely investigated, and excellent results have been obtained. For example, in 2014, Pidko and coworkers reported a very high activity for FA dehydrogenation using a ruthenium PNP-pincer complex, which provides a TOF of 257000 h\(^{-1}\) and TON of 706500 at 90 °C in DMF in the presence of an amine.\[32\]

Meanwhile, the Xiao group has been developing transfer hydrogenation with cyclometallated [Cp*Ir(L)Cl] complexes using FA as the hydrogen source, and found that the Ir-hydride intermediates could be intercepted not only by the iminium cations, but also by protons to release H\(_2\). In 2013, they reported a type of cyclometallated Ir-N^C complexes for the dehydrogenation of HCO\(_2\)H–NEt\(_3\) mixtures to give H\(_2\) and CO\(_2\) under mild conditions with no CO formation, achieving high turnover frequencies up to 147000 h\(^{-1}\) at 40 °C.\[116\]

Most of the above mentioned catalytic systems for FA dehydrogenation require
bases (e.g. amine) or additives (e.g. LiBF₄) in organic solvents. Although several catalysts have been reported for FA dehydrogenation in the absence of bases or additives, these reactions were conducted in organic solvents. For practical application, the dehydrogenation of FA in water without bases or additives is highly preferable. At present, only a few catalytic systems have been reported to be active in water in the absence of bases or additives. For example, in 2009, Himeda used a pH-dependent iridium-bipyridine catalyst for FA dehydrogenation, achieving a TOF of 14000 h⁻¹ at 90 °C without bases or additives in water. In 2014, Wang, Himeda and coworkers reported an iridium-biimidazole complex with a TOF of 34000 h⁻¹ at 80 °C, the highest TOF reported for FA dehydrogenation in water without bases or additives.

The FA dehydrogenation activity in water is much lower in the absence of bases or additives, and the available catalytic systems are limited to iridium complexes with aromatic bipyridine, bipyrimidine and biimidazole ligands. In Chapter 3, an iridium complex with a nonaromatic N,N'-diimine ligand was found to be highly effective for the base-free hydrogenation of CO₂ in water. Since FA dehydrogenation is the reverse reaction of CO₂ hydrogenation, the Ir-N,N’ diimine complex was subsequently studied for the dehydrogenation of FA, which is described in this chapter.

4.2 FA Dehydrogenation with Ir-N,N’ Diimine Complex in Water

4.2.1 FA dehydrogenation reaction

As expected, gas evolution was achieved for the dehydrogenation of FA with complex 11 and 12, and the results are listed in Table 4.1. The evolved gas mixture is composed of H₂ and CO₂ (1:1) without detectable levels of CO (Appendix Scheme C.1), suggesting that the reaction undergoes dehydrogenation instead of
dehydration.

Table 4.1 Dehydrogenation of FA in water using complexes 11 and 12

General conditions: No reaction occurred in the absence of catalysts. Each reaction was repeated at least twice with an error less than 5%. The volume of H<sub>2</sub> evolved was measured at the specified time. TON was estimated based on the H<sub>2</sub> amount in the same time interval. Con. refers to conversion of FA. <sup>a</sup>1.0 μmol of complex, 10.0 mL of H<sub>2</sub>O, 10.0 mmol of FA, TOF was calculated based on the conversion in the first 2 min. <sup>b</sup>1.0 μmol of complex, 10.0 mL of H<sub>2</sub>O, 50.0 mmol of FA, TOF was calculated based on the conversion in the first 20 s.

Using complex 11, 10.0 mmol of FA can be completely dehydrogenated within 20 min at 60 °C, giving an initial TOF of 50000 h<sup>-1</sup> (Table 4.1, entry 1). Under the same conditions, the reaction with complex 12 provides a lower TOF of 30000 h<sup>-1</sup> (Table 4.1, entry 2). When the temperature is increased to 90 °C, a TOF as high as 487500 h<sup>-1</sup> can be achieved using complex 11 (Table 4.1, entry 3). The time course of gas evolution using complex 11 at 90 °C shows that over 300 mL of gas was evolved in the first minute and the FA conversion reached 95% after 10 min (Scheme 4.1). Complex 12 also shows a good TOF of 375000 h<sup>-1</sup> at 90 °C (Table
4.1, entry 4). Other N,N’ ligands were also screened for this transformation; however, they all showed lower reactivity (Appendix, Table C.1).

![Graph showing gas volume over time](image)

**Scheme 4.1** Time course of gas evolution using complex 11 at 90 °C

### 4.2.2 Reaction mechanism study

![Graph showing Arrhenius fit](image)

**Scheme 4.2** Arrhenius fit of initial TOF values for dehydrogenation of FA. Reaction conditions: complex 11 (1.0 μmol), FA (1.0 M, 10.0 mL), 20 °C, 40 °C, 60 °C, 80 °C.

The dependence of dehydrogenation rate on temperature, catalyst concentration, FA concentration and pH value was then investigated using complex 11. The reaction rate increases with temperature, with the temperature dependence of the ini-
tial rates following the Arrhenius equation (Scheme 4.2). The estimated apparent activation energy (Ea) for FA dehydrogenation is 72.1 kJ mol\(^{-1}\), which is in the typical range of noble-metal catalyzed dehydrogenation of FA.\(^{66, 110, 125, 128}\)

The rate dependence on concentrations of complex 11 and FA was examined. The double logarithmic plots of the initial rate against the concentration of complex 11 and FA both show linear dependence (Scheme 4.3). These results show that this reaction proceeds with an order of 0.89 with respect to complex 11 and indicate that complex 11 is converted into a monomeric active species rapidly. The
reaction order with respect to FA was estimated to be 0.41 (approximate 0.5), which implies that only one HCO$_2^-$ coordinates to the iridium center in the transition state and that an equilibrium is probably involved between [Ir]+HCO$_2^-$ and [Ir]-HCO$_2^-$, the latter of which undergoes the dehydrogenation (see below).

$$HCOOH \overset{K_1}{\rightleftharpoons} HCOO^- + H^+ \quad (4.2)$$

$$Ir + HCOO^- \overset{K_2}{\rightleftharpoons} Ir-OOCH \quad (4.3)$$

$$Ir-OOCH \xrightarrow{k} P \quad (4.4)$$

If we assume that the dehydrogenation can be simplified by the equations 4.2-4.4, with equation 4.4, i.e. decarboxylation to generate the iridium hydride, being the turnover limiting step, a rate expression for the dehydrogenation can be derived as follows. $k$ is the rate constant of the product (P) formation step; $K_1$ is the equilibrium constant of eqn. 4.2; $K_2$ is the equilibrium constant of eqn. 4.3. [Ir] is the concentration of the iridium aqua complex. Applying steady-state approximation to [Ir-OOCH] and [HCOO$^-$], we have:

$$\text{Rate} = \frac{d[H_2]}{dt} = k[Ir-OOCH] = kK_2[HCOO^-][Ir] \quad (4.5)$$

since $[HCOO^-][H^+] = [HCOO^-]^2 = K_1[HCOOH]$, the reaction rate from eqn. 4.5 can be described as 4.6,

$$\frac{d[H_2]}{dt} = kK_2K_1^{0.5}[Ir][HCOOH]^{0.5} = k'[Ir][HCOOH]^{0.5} \quad (4.6)$$

Equation 4.6 agrees with the observations made above. In turn, this supports the assumption that the dehydrogenation is likely to be rate-limited by the step of decarboxylation.

Scheme 4.4 shows the TOF values obtained in the FA-HCO$_2$Na mixture solution at various pH values. The highest TOF value (72500 h$^{-1}$) was obtained at pH 2.8. The UV-Vis absorption spectra results at pH 2 to 13 (Appendix, Scheme C.2) show that the pKa1 of complex 11 due to deprotonation is around 9.0. Because the protonation status of 11 remains the same at pH < 7.3, the pH dependence of de-
hydrogenation may not be due to the deprotonation status of the ligand. The increase in TOF with decreasing pH from 8.0 to 2.8 indicates the importance of the hydronium ion (H$_3$O$^+$) concentration for this reaction. Meanwhile, the decrease in TOF with decreasing pH from 2.8 to 1.9 is consistent with the involvement of HCO$_2^-$ species (eqn. 4.3) in this reaction, the concentration of which decreases at low pH. It is also consistent with the result obtained for neat FA (anhydrous) dehydrogenation under the same conditions, where no reaction was detected, because nearly neither H$_3$O$^+$ ions nor HCO$_2^-$ exists in anhydrous FA.

![Scheme 4.4 pH dependence of the initial TOF](image)

**Scheme 4.4** pH dependence of the initial TOF

Reaction conditions: complex 11 (1.0 μmol), 60 °C, FA/HCO$_2$Na (1.0 M, 10.0 mL).

Based on the results discussed above and the NMR studies (see Appendix C), a possible reaction mechanism was proposed (Scheme 4.5). The catalytic cycle likely starts from the water coordinated iridium complex A, which is derived from complex 11 in aqueous FA solution. Subsequent coordination of HCO$_2^-$ to complex A forms the formato complex B (step I). After the release of CO$_2$ upon decarboxylation, the iridium hydride complex C is formed (step II), which was detected by NMR (δ = -12.20 ppm, Appendix, Scheme C.3) in basic solutions. Next, the hydride C reacts with a hydronium ion (H$_3$O$^+$) to produce H$_2$ (step III), which
is accompanied by the regeneration of aqua iridium complex A.

Scheme 4.5 Catalytic cycle of FA dehydrogenation

To further understand this process, a kinetic isotope effect study was performed using complex 11. As shown in Table 4.2, when the substrate HCO$_2$H was replaced with deuterated DCO$_2$H, the reaction rate decreased considerably. The KIE is 2.3 when DCO$_2$H replaces HCO$_2$H (Table 4.2, entry 2), but 1.7 when HCO$_2$D replaces HCO$_2$H (Table 4.2, entry 3). A KIE of 4.0 was obtained with DCO$_2$D in D$_2$O (Table 4.2, entry 4). The lower KIE values (Table 4.2, entries 2, 3) may be due to H-D scrambling at iridium. These results indicate again that the cleavage of the formate H-CO$_2$- bond is most likely involved in the rate-determining step under the given reaction conditions. In addition, Ir-H was not observed in acidic solution by $^1$H NMR (Appendix, Scheme C.4). Thus the generation of [Ir]-H (step II), not the hydrogen elimination (step III), is proposed to be the rate-determining step.

$^a$ Reaction conditions: complex 11 (1.0 μmol), FA solution (1.0 M, 10.0 mL), 60 °C; $^b$ TOF was calculated in the first 2 min; $^c$ KIE = TOF(entry 1)/TOF(entry n) (n = 2, 3, 4).

4.2.3 Catalytic stability test

The stability of our catalyst was also investigated. For the catalyst recycling test (Scheme 4.6), 20.0 mmol of FA was consumed in each cycle when using 2.0 μmol of complex 11 at 60 °C. This catalyst functioned continuously for 37 cycles with only slightly declining activity. When using the in situ generated iridium catalyst with ligand L$^{18}$ (Ir:L = 1:5) for FA dehydrogenation at 80 °C and charging FA at certain time intervals, a total TON of 2400000 was achieved in approximately 14 hours.
Scheme 4.6 Recycles of the dehydrogenation of FA.

Reaction conditions: complex 11 (2.0 μmol), FA (2.0 M, 10.0 mL), 60 °C. FA (20.0 mmol) was added into the reaction at the beginning of each cycle. Part of (a) is enlarged as shown in (b).

The FA dehydrogenation can also take place smoothly in a closed system under pressurized conditions. In a 300 mL autoclave, the total pressure reached 4.4 MPa after 6 hours when using 1.0 μmol of \textit{in situ} formed complex 12 to dehydrogenate FA (5.0 M, 50.0 mL) at 60 °C (less than 0.3% of FA left behind), indicating that high pressure of H₂ can be supplied using this catalyst.
4.3 Summary

In summary, the water-soluble iridium complexes such as 11 and 12 with nonaromatic N,N’-diimine ligands show extremely high FA dehydrogenation activity in water. Without the addition of any bases or additives, a TOF of up to 487500 h\(^{-1}\) with complex 11 and a TON of 2400000 with the \textit{in situ} prepared catalyst from [IrCp*Cl\(_2\)]\(_2\) and L18 were obtained. The high activity and good stability of these catalysts make hydrogen generation from FA more feasible for potential applications.

4.4 Experimental Section

4.4.1 General information

**Instruments:** Details have been given in Chapters 2 and 3. GC analysis results were obtained with Techcomp GC7890 II equipped with a TCD and a FID.

**Chemicals:** Formic acid (98%) and [IrCp*Cl\(_2\)]\(_2\) were purchased from J&K. Sodium formate was purchased from Sinopharm Chemical Reagent Co. Ltd.

4.4.2 Procedure for catalytic dehydrogenation of FA

An aqueous catalyst stock solution was prepared freshly before use and the reactions were carried out without protection.

First, 10.0 mL of the FA aqueous solution and a stir bar were placed in a Schlenk tube equipped with a side branch and rubber septa. Afterwards, the tube was preheated at given temperature (e.g. 60 °C) in a water bath until the required temperature was attained. Then, freshly prepared aqueous catalyst stock solution was injected into the reaction through the septa, and the timing started immediately. The side branch was connected to the gas collection apparatus (standard water displacement apparatus, using a graduated cylinder to determine volume).
The volume of gas generated was recorded.

For the reaction carried out in neat FA, FA was dehydrated using anhydrous Na$_2$SO$_4$ for 3 h before use. 10.0 mL of dehydrated FA and stir bar were placed in a Schlenk tube, and preheated at 60 °C for 10 min. Then complex 11 (1.0 μmol) was added in and the tube was sealed immediately. No observable gas evolution was detected within 20 min. Next, 5.0 mL of water was injected into the reaction, and gas evolution occurred gradually. Thus the FA dehydrogenation using complex 11 requires H$_3$O$^+$ and HCO$_2^-$.

For the long-time reaction, a stir bar, water (7.0 mL) and FA (2.2001 g, 98%) were placed in a Schlenk tube equipped with a side branch and rubber septa. After the tube was preheated at 80 °C in water bath, the stock solution of in situ generated iridium catalyst (1.0 mL, 0.05 μmol of [IrCp*Cl$_2$]$_2$ and 0.5 μmol of L18) was injected into the reaction through the septa, and the timing was started. The side branch was connected to the gas collection apparatus. At the reaction times of 80 min, 200 min, 270 min and 400 min, 2.7503 g, 1.9310 g, 2.3395 g and 2.1102 g of FA were added, respectively. After 14 hours of reaction, no gas was observable, and the residue of FA was determined to be 0.111 mmol by ion chromatograph. Thus the amount of the reacted FA was as follows:

\[
n_{FA} = \frac{2.2001 + 2.7498 + 1.9310 + 2.3385 + 2.1102}{46.03} \times 1000 \times 98\% - 0.111
\]

\[
= 241.10 \text{ mmol}
\]

Thus,

\[
TON = \frac{241.10 \times 1000}{0.1} = 2,411,000 \approx 2,400,000.
\]

4.4.3 Calculation of TON and TOF

TON was calculated according to eqn. 4.2. No blank reaction was observed with-
out catalyst. The solvent and water vapor was neglected.

\[
\text{TON} = \frac{V_{\text{total}}}{2 \cdot V_{m,H_2,20^\circ C} \cdot n_{\text{cat}}} \quad (4.2)
\]

Calculation of \(V_{m,H_2,20^\circ C}\) was carried out using van der Waals eqn. 4.3.

\[
V_{m,H_2,20^\circ C} = \frac{RT}{p} + b - \frac{a}{RT} = 24.16 \text{ L} \cdot \text{mol}^{-1} \approx 24 \text{ L} \cdot \text{mol}^{-1} \quad (4.3)
\]

R: 8.3145 m³ Pa mol⁻¹ K⁻¹

T: 298.15 K

p: 101325 Pa

b: 26.7·10⁻⁶ m³·mol⁻¹

a: 2.49·10⁻¹⁰ Pa·m³·mol⁻²

Calculation of \(V_{m,CO_2,20^\circ C}\) was carried out using van der Waals eqn. 4.4.

\[
V_{m,CO_2,20^\circ C} = \frac{RT}{p} + b - \frac{a}{RT} = 24.10 \text{ L} \cdot \text{mol}^{-1} \approx 24 \text{ L} \cdot \text{mol}^{-1} \quad (4.4)
\]

R: 8.3145 m³ Pa mol⁻¹ K⁻¹

T: 298.15 K

p: 101325

a: 36.5·10⁻¹⁰ Pa·m³·mol⁻²

b: 42.7·10⁻⁶ m³·mol⁻¹

The TOF calculation is time related (h⁻¹) based on the TON calculation. For example, at 90 °C, using 0.002 mol % (1.0 μmol) complex 11 in 5.0 M aqueous solution of FA, 130 mL gas was released in the first 20 s, thus.

\[
\text{TOF} = \frac{\frac{130}{0.002} \times \frac{3600}{20}}{20} = 487.500 \text{ h}^{-1}
\]

4.4 Gas composition analysis

A GC with a TCD and a FID detector equipped with a methaniser confirmed the products of FA decomposition were H₂ and CO₂ with no detectable level of CO.

The molar ratio of H₂ and CO₂ was measured to be approximate 1:1 after calibra-
tion (twice, experimental error less than 4%). Since we used the water replacement method to quantify the amount of H₂, the gas composition after water absorption was also tested. The amounts of H₂ and CO₂ were approximately equal because most of our reactions finished within 20 minutes, a short time insufficient for considerable amounts of CO₂ to be absorbed by tap water especially when considering the TOF measurement (within the initial 2 min).
Chapter 5 Iodide-Promoted Dehydrogenation of FA on a Rhodium Complex
5.1 Introduction

As discussed previously, hydrogen generation from FA has attracted much attention in recent years. This chemistry could provide a technology for hydrogen supply for e.g. small mobile or stationary applications. Accordingly studies into catalytic dehydrogenation of FA have been carried out by a number of research groups, with some reporting excellent TOFs. In the arena of homogeneous catalysis, the highest TOF of 487500 h⁻¹ was obtained using the Ir-N,N’ diimine complex which was discussed in Chapter 4. [185] However most of the reported catalysts consist of relatively complicated or expensive bidentate/tridentate ligands along with the metal center, although they can be highly active in the dehydrogenation. Considering the practicality of the FA dehydrogenation in real life, developing efficient catalyst systems without using complicated or delicate ligands would be preferable for FA dehydrogenation.

Halide ions, one of the most common and simplest additives and ancillary ligands for transition metal complex catalysts, have frequently been found to exert some unusual influence on catalytic reactions. [186, 187] In particular, the significant promoting effect of the iodide anion in hydrogenation and transfer hydrogenation reactions has been recognized. [187-190] Although the mechanistic details of the iodide effect on these reactions remain unclear, its softness, trans effect and size may play a role. Xiao’s group has reported the precatalyst [RhCp*Cl₂]₂ to catalyze the transfer hydrogenation of N-heterocycles with the FT azeotrope in the presence of halide ions and particularly iodide. [188] The hydrogen is derived from the decomposition of FA, showing that the [RhCp*Cl₂]₂–X⁻ combination is capable of FA dehydrogenation. Therefore in this chapter, the dehydrogenation of HCO₂H/NEt₃ with [RhCp*Cl₂]₂ was investigated, including especially the effect of I⁻.
5.2 [RhCp*Cl₂]₂ Catalyzed FA Dehydrogenation

5.2.1 FA dehydrogenation in the presence of additives

The [RhCp*Cl₂]₂ catalyzed FA dehydrogenation was examined in the absence or presence of halide anions at 60 °C in the FT azeotrope, where the F/T molar ratio is 2.5. The amount of evolved gas was determined by water displacement method, and GC confirmed the products to be H₂ and CO₂ (1:1 ratio) with negligible level of CO (Appendix, Scheme D.1). As shown in Table 5.1 and Scheme 5.1, both the TOF and TON are increased on the addition of potassium halides, with KI enabling the fastest reaction. In its presence the initial TOF increased most significantly to 4375 h⁻¹ from 625 h⁻¹ in its absence. Comparing the TOF values obtained with KI, NaI and LiI, it can be concluded that this activity enhancement arises from the halide anions rather than the alkali cations. In addition, the presence of I⁻ makes this catalyst more productive, increasing the TON from 151 to 706 (at 40% FA conversion, Table 5.1, entries 1, 5) after 30 min.

* General reaction conditions: 5.0 μmol of [RhCp*Cl₂]₂, 1.0 mmol of alkali halide, 1.5 mL of FT azeotrope, at 60 °C. Approximately 16 mmol of FA is included in 1.5 mL FT azeotrope. \( ^b \) The amount of gas and TON were recorded and calculated after 30 min reaction. \( ^c \) TOFₘₐₓ
was calculated based on the volume of evolved gas from 3 to 6 min after the reaction had started to rule out the influence of temperature fluctuation due to the injection of FT solution and to avoid the initial induction period (See Figure 5.1). Each reaction was repeated at least twice with an error less than 5%. No reaction was observed without catalyst.

![Scheme 5.1](image)

**Scheme 5.1** Time course of gas evolution during the dehydrogenation of FA.

Reaction conditions: 5.0 μmol of [RhCp*Cl₂]₂, 1.0 mmol of inorganic salts (6 mol%), 1.5 mL of FT azeotropic solution, at 60 °C.

Other rhodium complexes as well as those based on iridium and ruthenium were also investigated as catalyst precursors in combination with I⁻ for FA dehydrogenation (Appendix, Table D.1). All the complexes tested showed very low activity, except for [Ru(p-cymene)Cl₂]₂, which gave a moderate TOF of 1500 h⁻¹. This value is 6 times higher than that of the reaction without I⁻ (Appendix, Table D.1, entries 2-3), indicating that the promoting effect of I⁻ is not limited to [RhCp*Cl₂]₂.

### 5.2.2 Kinetics of FA dehydrogenation

To gain an understanding of the dehydrogenation reaction, the rate dependence on temperature, catalyst concentration, KI amount and FA/triethylamine (TEA) ratio were investigated. The reaction rate increases with temperature, and the tempera-
ture dependence of the initial rates follows the Arrhenius equation (Scheme 5.2). The apparent activation energy (Ea) for the FA dehydrogenation is estimated to be ca 64 kJ mol\(^{-1}\), which is near the typical range of noble metal catalyzed hydrogen generation from FA in aqueous solution.\[125, 128, 185\]

![Scheme 5.2](image)

**Scheme 5.2** (a) Time course of gas evolution during the dehydrogenation of FA at 30 °C to 80 °C; (b) Arrhenius plot of initial rate for FA dehydrogenation. Reaction conditions: 5.0 μmol of [RhCp*Cl\(_2\)] and 1.0 mmol of KI in 1.5 mL of FT azeotrope at temperatures from 30 °C to 80 °C; The initial rate refers to the fastest rate obtained right after the short induction period. Thus the Ea value derived here is only an estimation of activation energy because log\(r\) is used instead of log\(k\).
The rate dependence on catalyst concentration [Rh] was explored using 0.1 ~ 5.0 μmol of [RhCp*Cl₂]₂ in combination with 500 μmol of KI in 1.5 mL of FT azeotrope at 60 °C (Appendix, Scheme D.2). The double logarithmic plot of the initial rate against the catalyst concentration shows a linear dependence on the [Rh] (Scheme 5.3). As can be seen, the reaction proceeds with an order of 0.90 with respect to the catalyst concentration [Rh], which is close to 1.0. This is consistent with a mononuclear rhodium species being involved in the catalytic cycle (also see below), and no other polymeric compounds are likely to be the active catalyst. Beyond the [Rh] concentration of 1.07 mM, the initial TOF declines gradually (Appendix, Scheme D.2b). This may result from catalyst aggregation at a higher concentration (vide infra).

Scheme 5.3 Plot of ln(initial rate of H₂ evolution) versus ln[Rh] ([Rh] means rhodium monomer concentration).

Conditions: 0.1 ~ 5.0 μmol of [RhCp*Cl₂]₂, 500 μmol of KI, 1.5 mL of FT azeotrope, at 60 °C.

The rate dependence on the concentration of KI was investigated using 0.8 μmol of [RhCp*Cl₂]₂ with 40 ~ 500 μmol of KI in 1.5 mL of FT azeotrope (Appendix, Scheme D.3). The reaction rate shows a fraction order of 0.68 on iodide concentration, up to [KI] ≈ 0.1 M (nKI = 160 μmol) (Scheme 5.4). This result in-
indicates that the iodide ion is likely to be involved in the rate-determining step (RDS) and equilibria prior to it.

![Graph](image_url)

**Scheme 5.4** Plot of Ln(initial rate of H\textsubscript{2} evolution) versus ln[KI].

Conditions: 0.8 \mu mol of [RhCp*Cl\textsubscript{2}], 40 ~ 500 \mu mol of KI, 1.5 mL of FT azeotrope, at 60 °C.

With different FA/TEA ratios, the time course of gas evolution was recorded as shown in Scheme 5.5a. The FT mixture solutions were prepared with the molar ratio of FA/TEA in the range of 2.25:1 to 3:1. Scheme 5.5b shows the variation of the initial TOF and TON with the FA molar fraction in the starting solution. As can be seen, the final TONs increase approximately linearly with increasing FA amount (arrow line). In contrast, the initial TOFs show a reverse dependence on the FA molar fraction, with more FA giving rise to lower TOFs. Since [HCOO\textsuperscript{-}] is reversely proportional to [HCOOH] in the FA/TEA mixture, the reverse dependence suggests that the dehydrogenation rate depends on [HCOO\textsuperscript{-}]. In line with this, no gas bubble was observed in neat FA and no Rh-H species was detected in neat FA either (Appendix, Scheme D.4). These observations appear to indicate that the dehydrogenation is rate-limited by the step of hydride formation, where coordination of the formate is necessary.
Scheme 5.5 (a) Time course of gas evolution during the dehydrogenation of FA in FT solution with different F/T ratio: 0.8 μmol of [RhCp*Cl\(_2\)], 320.0 μmol of KI, 1.5 mL of FT solution with the mole ratio of FA/TEA in the range from 2.25:1 to 3:1, at 60 °C. Each reaction was repeated twice. The blue -▲- line represents FA dehydrogenation conducted in FT azeotropic solution and the blue -▼- line represents reaction conducted in physically mixed FT solution (2.5:1). (b) TON and TOF values observed in FT solutions with different FA/TEA ratios. TON was measured using the final gas amount as shown in (a), from 20 to 50 min. The TOF was calculated based on the volume of evolved gas from 3 to 6 min after the reaction had started to rule out the influence of temperature fluctuation due to the injection of FT solution and to avoid the initial induction period.

In addition to TEA, other amines were also tested for the reaction as shown in Scheme 5.6 (the pKa value of the amines are listed in Appendix, Table D.2). Tertiary amines show superior reactivity compared with primary and secondary
amines. This may result from the latter two types of amines being better hydrogen bond donors, reducing the concentration of free iodide ions needed for higher dehydrogenation rates (*vide supra*).

**Scheme 5.6** FA dehydrogenation using various amines: 0.8 μmol of [RhCp*Cl$_2$]$_2$, 320 μmol of KI, 1.5 mL of FA/amine (2.5:1) solution, at 60 °C.

### 5.2.3 The structure of active catalysts

Effort was then made to investigate the role of I$^-$ in this reaction. Firstly, a contrast experiment was conducted using [RhCp*Cl$_2$]$_2$ and [RhCp*I$_2$]$_2$ as catalyst precursors. As shown in Scheme 5.7, without KI, the FA dehydrogenation rates for both rhodium complexes are low and essentially identical. When KI is added, both reactions are accelerated considerably and to a similar extent. These findings rule out the possibility of the iodide effect arising from the iodide-ligated rhodium dimer [RhCp*I$_2$]$_2$, and suggest that the same active catalyst is generated in the presence of I$^-$ regardless of which rhodium precursor is used. The necessity for a large excess of coordinating I$^-$ also indicates that the active catalyst is less likely to be other forms of dimeric Cp*Rh(III)-I species. It is noted that replacing KI with the same amount of KCl has only an insignificant effect on the
dehydrogenation catalyzed by [Cp*RhI]_2 (Appendix, Scheme D.5).

![Graph showing gas amount vs. time for different rhodium complexes with and without KI.](image)

**Scheme 5.7** FA dehydrogenation using [RhCp*Cl]_2 and [RhCp*I]_2: 5.0 μmol of [RhCp*X]_2, 1 mmol of KI when added, 1.5 mL of FT azeotrope, 60 °C.\textsuperscript{[191]}

The FA dehydrogenation with [RhCp*Cl]_2 at room temperature in the absence or presence of I\textsuperscript{−} was monitored by \textsuperscript{1}H NMR spectroscopy over a period of 72 h (Appendix, Scheme D.6; for details see the experimental section). Comparing Scheme D.6a and D.6b (Appendix) shows that the FA (indicated by the formate proton signal) was consumed to a greater extent after 72 h in the presence of I\textsuperscript{−} (54 % vs. 18 % FA conversion), which is consistent with the results from Figure 5.1. The hydride part (-5 ~ -22 ppm) of Scheme D.6 is enlarged and shown as Scheme 5.8 here. Without KI (Scheme 5.8a), a Rh-H hydride triplet at -8.87 ppm along with a new chemical shift at 1.90 ppm (Cp* proton, Appendix, Scheme D.6e) appeared instantly (less than 5 min) upon mixing the rhodium precursor with FT azeotrope in CDCl\textsubscript{3}, indicating quick formation of a binuclear rhodium species with a bridging hydride.\textsuperscript{[192]} Other rhodium species bearing bridging hydride ligands started to appear later (-11.71 and -20.39 ppm). In the presence of KI (Scheme 5.8b), the NMR spectra show that similar rhodium species are formed quickly in addition to a new peak at -8.85 ppm, which overlaps with a slightly
smaller peak centred at -8.87 ppm (Appendix, Scheme D.6g). The latter presumably arises from the same species as the one in the absence of the iodide. However, the peak at -11.72 ppm disappeared after 5 h while the one at -8.85 ppm disappeared after 24 h, accompanied with the appearance of new, unknown rhodium species with bridging hydride.

**Scheme 5.8** $^1$H NMR spectra of [RhCp*Cl$_2$]$_2$ reacting with FT azeotrope in CDCl$_3$ (hydride part): (a) without KI; (b) in the presence of KI (250 μmol).

General conditions: 5.0 μmol of [RhCp*Cl$_2$]$_2$, 0.1 mL of FT azeotrope, room temperature. Timing started after the injection of FT solution.

It is also worth noting that there is no visible doublet hydride resonance during
the catalytic reaction, again indicating that the dehydrogenation is likely to be turnover-limited by the step of hydride formation. Since gas evolution was observed over the entire period of 72 h in both cases, the disappearance of the triplets mentioned is consistent with the corresponding binuclear rhodium species being not active catalyst.

**Scheme 5.9** Mass spectrometry of [RhCp*Cl₂]₂ reacting with FT azeotrope in methanol. Conditions: 1.6 μmol of [RhCp*Cl₂], 0.2 mL of FT azeotrope, 1.0 mL of methanol, room temperature. Upper: without KI; lower: 120 μmol of KI.

Mass spectrometry was then employed in an attempt to identify these rhodium species. Scheme 5.9 shows the mass fragment of [RhCp*Cl₂]₂ reacting with the FT azeotrope in methanol within 5 min after the reaction had started (see Appendix, Scheme D.7 for full spectrogram). In the absence of KI, the mass peak at m/z 557.0228 can be ascribed to [Rh₂Cp*₂Cl(H)(OCHO)]⁺ (d, Scheme 5.10, *vide infra*), a rhodium dimer complex containing a bridging hydride and a bridging formato ligand (¹H NMR: 7.39 ppm).¹⁹³, ¹⁹⁴ When KI was added, the newly generated mass peak at m/z 648.9554 supports the formation of [Rh₂Cp*₂I(H)(OCHO)]⁺ (D, Scheme 5.10),¹⁹⁵ an analogue of d, while the one at
m/z 730.8639 may correspond to [Rh₂Cp*₂(H)I₂]⁺ (E, Scheme 5.10). Each of these species is expected to display a triplet hydride signal in their ¹H NMR spectra and thus appears to correspond well to those revealed in Scheme 5.8.

5.2.4 Proposed reaction mechanism

Scheme 5.10 Plausible reaction mechanism for the dehydrogenation of FA using [RhCp*Cl₂]₂ in the absence (1) or presence (2) of I⁻.

Taken together, a plausible reaction mechanism is tentatively suggested for the [RhCp*Cl₂]₂ catalysed dehydrogenation of FA (Scheme 5.10). With or without KI, the dimeric [RhCp*Cl₂]₂ firstly dissociates under the reaction conditions, turning into the catalytically active monomeric rhodium species a in the absence of I⁻ and C in its presence. The latter is in fast equilibrium with the formato A, the iodo analogue of a. Subsequently, the rhodium hydrides b and B are formed from a and A via decarboxylation, protonation of which releases H₂ and regenerates the
active catalysts.

During the catalytic turnover, the spectator dimeric species d, D and E containing bridging hydride are formed upon dimerization of the monomers in the catalytic cycle. As the reaction progresses, other unknown rhodium species are formed as shown by the $^1$H NMR in Schdme 5.8. These species are not considered as reactive species. However, they may be in fast equilibrium with the catalytically active monomers; otherwise the catalyst would deactivate quickly.[193]

As indicated above, the overall dehydrogenation is likely to be controlled by the step of hydride formation in turnover.[198, 199] Thus, the promoting effect of iodide can be ascribed to decarboxylation from A being easier than from a, which in turn may be due to the iodide being a better ligand to the Rh(III) than the chloride.[200]

Since the decarboxylation could proceed via a transition state involving dissociation of the formate to form an ion pair,[117, 121, 199, 201, 202] a better coordinating iodide anion would be expected to stabilise better the transition state that contains a positively charged Rh(III). However, excess iodide will shift the equilibrium between C and A to favour C, thereby giving rise to the saturation kinetics seen above (Scheme 5.4).

5.2.5 Catalytic stability test

The stability of this catalyst system for FA dehydrogenation was also investigated. During a single FA decomposition reaction using 5.0 μmol of [RhCp*Cl$_2$]$_2$ and 1.0 mmol of KI in 1.5 mL of FT azeotrope at 60 °C, the catalyst is observed to lose activity eventually (at con. < 50%, Scheme 5.1), and gas evolution could not be fully recovered with the addition of either formic acid or FT azeotrope (Appendix, Scheme D.8). This could be caused by the irreversible formation of some deactivated rhodium hydride species as a result of the consumption of FA (Appendix, Scheme D.9). Nevertheless, the addition of KI prolongs the life time
(TON) of the catalytic system; in its absence, the catalyst is of low activity right from the beginning (Scheme 5.7). One way to keep this reaction going is to add an additional amount of FA into the system at certain time intervals. This is shown in Scheme 5.11, where more than 1000 mL of H₂ were released upon seven consecutive additions of FA, although the dehydrogenation rate became slower progressively. Thus the TON was enhanced from 706 (Table 5.1) to over 2540.

Scheme 5.11 Longer time reaction with intermittent addition of FA.

Conditions: 5.0 μmol of [RhCp*Cl₂], 1.0 mmol of KI, 1.5 mL of FT azeotrope, 60 °C. The amount of FA added was roughly based on the amount of evolved gas, 0.12 mL, 0.12 mL, 0.12 mL, 0.12 mL, 0.15 mL, 0.15 mL.

5.3 Summary

In this chapter, the FA dehydrogenation catalysed by a simple, commercially readily available rhodium catalyst, [RhCp*Cl₂]₂, is studied and the catalytic activity is found to be enhanced by the addition of halide ions. The catalytic activity increases with the atomic number of halide ions, and with I⁻ the activity is increased 7 folds. Not only does the iodide ion increase the reaction rate, it also prolongs the catalyst lifetime. Kinetic studies and NMR monitoring suggest the active catalyst to be mononuclear in equilibrium with binuclear hydrides outside
of the catalytic cycle. The catalytic turnover appears to be controlled by the rate of hydride formation, which is facilitated by iodide anions coordinated to the Rh(III) center.

5.4 Experimental Section

5.4.1 General information

**Instruments:** Details have been given in Chapter 2, 3 and 4.

**Chemicals:** [RhCp*Cl₂]₂, formic acid, triethylamine (TEA), 1-methylpiperidine, piperidine, dibutylamine, octylamine, and cyclohexylamine were purchased from Aldrich. A second bottle of [RhCp*Cl₂]₂ was purchased from Energy Chemical. KF, KCl, KBr, KI, NaI, and LiI were purchased from Fisher. [RuCl₂(p-cymene)]₂ was purchased from Alfa Aesar. RhCl₃•xH₂O and [Rh(OAc)₂]₂ were purchased from Shanxi Kaida Chemical Engineering Co. Ltd. [IrCp*Cl₂]₂, [Rh(nbd)₂]BF₄, [Rh(cod)₂]BF₄, and [Rh(cod)Cl]₂ were purchased from J&K. FT azeotrope was distilled and stocked under argon.

5.4.2 Synthesis and characterization of ligands and complexes

[RhCp*Cl₂]₂ was prepared by referring to the literature. A suspension of [RhCp*Cl₂]₂ (0.1 mmol, 61.8 mg) and NaI (1.0 mmol, 149.9 mg) in acetone (30 mL) was refluxed under argon overnight and the solvent was then evaporated. The residual was dissolved in dichloromethane (DCM) and filtered. Dark violet crystals were obtained after recrystallization from DCM/petroleum ether. ¹H NMR (400 MHz, CDCl₃) δ (ppm) = 1.99 (s, 30H).

5.4.3 In situ ¹H NMR analysis

The identification of intermediate d is based on a reported rhodium dimer com-
plex: \[^{1}H\text{NMR (400 MHz, CDCl}_3\text{): }\delta (\text{ppm}) = -8.87 \ (t, J_{\text{RhH}} = 26.8 \text{ Hz, Rh-}I\text{-Rh), 1.90 (s, C}_5\text{Me}_5\text{), 7.39 (t, }J_{\text{HH}} = 3.2 \text{ Hz, HCO}_2\text{). MS (ESI, }m/z\text{): 557.0 ([M]\\text{^+}).}

\text{D is identified as a structure analogue of d: }\[^{1}H\text{NMR (400 MHz, CDCl}_3\text{): }\delta (\text{ppm}) = -8.85 \ (t, J_{\text{RhH}} = 30.4 \text{ Hz, Rh-}I\text{-Rh), 1.89 (s, C}_5\text{Me}_5\text{), 7.07 (t, }J_{\text{HH}} = 3.2 \text{ Hz, HCO}_2\text{). MS (ESI, }m/z\text{): 648.9 ([M]\\text{^+}).}

The structure of \(E\) is speculated based on the following data: \(^{1}H\text{NMR (400 MHz, CDCl}_3\text{): }\delta (\text{ppm}) = -11.72 \ (t, J_{\text{RhH}} = 32.8 \text{ Hz, Rh-}I\text{-Rh), 1.96 (s, C}_5\text{Me}_5\text{). MS (ESI, }m/z\text{): 730.9 ([M]\\text{^+}).}

During the \textit{in-situ} \(^{1}H\text{NMR test, various rhodium hydrides were observed with the prolonged reaction time or addition of more FA. It is difficult to assign these hydrido proton peaks, because they may be one (several) of or a mixture of all those unknown intermediates (various bridging H mode) which were formed due to the lack of H}^+\text{ gradually. Meanwhile it explains the importance of maintaining the FT ratio during the long time reaction.}
Chapter 6 Conclusions and Perspectives
6.1 Conclusions

This thesis describes efforts made to tackle the challenges in homogeneous hydrogenation of CO$_2$ to formate/formic acid and formic acid dehydrogenation. From the previous chapters, we can see that problems were identified in this area and new solutions were discovered out of our research. Scheme 6.1 gives a summary of the research covered in this thesis.

![Scheme 6.1 Summary of the research of the thesis](image)

(1) Cyclometallated Ir-N$^\text{C}$ complexes and Ir-N,N’ diimine complexes have been developed and found to be effective for the hydrogenation of CO$_2$ to FA/formate and for FA dehydrogenation. These results not only extend the ligand scope for this transformation, which previously was concentrated on the phosphine ligands, pincer ligands and aromatic N,N’ ligands, but also provide potential catalysts for hydrogen storage via CO$_2$ cycling.

(2) From the view point of atom economy and green chemistry, this thesis has accomplished the base-free aqueous hydrogenation of CO$_2$ to FA and FA dehydrogenation under mild conditions.

(3) Chapter 2 and Chapter 4 described the detailed mechanism study on CO$_2$ hydrogenation and FA dehydrogenation, which to some extent reveals the role of solvent (H$_2$O)/additive (I$^-$) playing in the reactions.
6.2 Deficiencies

Apart from the achievements summed up above, there are several non-negligible deficiencies in this thesis and much more work need to be done considering the following points:

(1) Chapter 2 should have studied more ligands and more details of the mechanism for a better understanding of the ligand structure influence on the catalytic activity.

(2) Water has been found to play an important role in the hydrogenation of CO$_2$ reaction described in Chapters 2 and 3; however it hasn’t been explained clearly.

(3) The water-soluble cyclometallated Ir-N$^\text{C}$ complex hasn’t been obtained in this thesis, which is expected to be effective towards the hydrogenation of CO$_2$ and FA dehydrogenation in water.

6.3 Perspectives

From the viewpoint of catalyst design, both the cyclometallated Ir-N$^\text{C}$ complexes and the Ir-N,N’ diimine complexes are worth further studying in terms of electronic property and hydrophilicity, e.g. via changing the substituents on the ligand ring or synthesizing the acyclic ligands.

Besides FA, methanol as another product of CO$_2$ hydrogenation is also of important industrial value. FA is usually the intermediate product for homogeneous hydrogenation of CO$_2$ to methanol. Thus with these highly efficient iridium catalysts, methanol could be possibly produced via catalyst integration. Similarly, other chemicals like formamide may also be obtained through this strategy.

These two types of iridium complexes may find themselves useful for other hydrogenation/dehydrogenation reactions, such as the reduction of esters or C=N
bonds etc., through the Ir-H hydride generated \textit{in situ}. Functionalized with chiral groups, these complexes may even be effective for asymmetric hydrogenation.

[163] The slightly larger solubility of H$_2$ in D$_2$O than that in H$_2$O is also possible to cause a reverse KIE, but the value should not be such distinct.

[168] $^1$H NMR results show that in the presence of PPh$_3$, the coordinating H$_2$O on complex 2 would be replaced. Appendix, Scheme B.3.

[191] The reactivity here is slightly lower compared with Scheme 5.1 because a different bottle of [RhCp*Cl₂]₂ was used.

[194] d is one of the most possible configurations based on [Rh2Cp*2Cl(H)(OCHO)]+.

[195] D is one of the most possible configurations based on [Rh2Cp*2IH(OCHO)]+.

[196] E is one of the most possible configurations based on [Rh2Cp*2H2]+.

[197] C is one of the most possible speculated configurations, but without direct support by experimental data.

[198] The possibility of the protonation step being the RDS cannot be ruled out, however, as the equilibrium between the monomer and dimer could render the concentration of the monomeric Rh-H too low to be detected by the 1H NMR.

[200] Although KBr and KCl also promote this reaction, their effect is much less significant than that of KI (Scheme 5.1), probably because the iodide is softer and a stronger nucleophile in protic solvents and hence is ex-pected to bind to the iridium more easily.

Appendixes

Appendix A

Scheme A.1 Detection of HCOOK and the determination of product amount with $^1$H NMR.
Reaction conditions: complex 3 (3.0 µmol), 1.0 M KOH MeOH solution (10.0 mL), 4.5 MPa CO$_2$/H$_2$ (1:2), 80 °C, 16h.

Scheme A.2 $^1$H NMR spectrum (400 MHz, D$_2$O) of reaction mixture
Reaction conditions: complex 8 (0.2 µmol), 1.0 M KOH/MeOH/H$_2$O (1:1) solution (10.0 mL), 5.0 MPa CO$_2$/H$_2$ (1:1), 40 °C, 1 h.
Appendix B

**Scheme B.1** CO₂ hydrogenation product detection with \(^1\text{H}\) NMR

Reaction conditions: complex 12 (0.25 μmol), H₂O (10.0 mL), CO₂/H₂ = 1/1 (5.0 MPa), 40 °C, 30 min.
Scheme B.2 Product detection of \( \text{CO}_2 \) hydrogenation (\( \text{H}_2 \)) performed in \( \text{H}_2\text{O} \) (a) and \( \text{D}_2\text{O} \) (b). Reaction conditions: complex 12 (0.25 μmol), 0.01 mmol of DSS (internal standard), \( \text{H}_2\text{O} \) or \( \text{D}_2\text{O} \) (10.0 mL), \( \text{CO}_2/\text{H}_2 = 1/1 \) (2.0 MPa); at 40 °C, 30 min. After reaction was cooled down in ice water, the autoclave was unsealed and 0.2 mmol of \( \text{Na}_2\text{CO}_3 \) was added into the solution. 0.5 mL of the product solution was taken out and submitted to the NMR machine.

Scheme B.3 \( ^1\text{H} \) NMR spectra of complex 13 in the presence of PPh\(_3\): the generation of new species indicates that the coordination of PPh\(_3\) occurred.
Scheme B.4 Reaction of complex 12 with H₂ (1.5 MPa) in CD₃OD/H₂O (0.1 mL CD₃OD + 0.03 mL H₂O) was tracked in Wilmad thick-wall NMR tube: Ir-H signal at δ = -12.09 ppm appeared within 5 min.

Scheme B.5 Reaction of complex 12 with H₂/CO₂ (1:1, total 1.2 MPa) in CD₃OD/H₂O (0.1 mL + 0.03 mL) was tracked: Ir-H signal at δ = -12.09 ppm and H-COOH signal at δ = 8.19 ppm appeared within 5 min.
**Scheme B.6** Reaction of complex 12 with H₂/CO₂ (1:1, total 1.2 MPa) in D₂O/H₂O (0.05 mL + 0.15 mL) was tracked in Wilmad thick-wall NMR tube.

**Scheme B.7** Detection of NH protons on complex 12 and the disappearance of NH protons with the addition of base in water by ¹H NMR at room temperature: H₂O/D₂O (0.2 mL + 0.3 mL); Na₂CO₃ (1.1 eqv.)

Scheme C.4 $^1$H-NMR spectra of HCO$_2$H in D$_2$O (red line, bottom), complex 11 in D$_2$O before (green line, middle)) and after (blue line, upper) reaction with HCO$_2$H.

NMR test procedure: First, 4.0 mg of complex 11, 0.2 mL H$_2$O and 1.0 mL D$_2$O were mixed together in an NMR tube to obtain the green line in Figure C.4. Subsequently, 10.0 μL HCO$_2$H was added, and the reaction was held at 80 °C for approximate 1 min until the bubbling stopped. The NMR tube was quickly sealed and submitted to obtain the blue line.

$^a$ Reaction conditions: 10.0 μmol of Rh or Ir (monomer), 1.0 mmol of KI, 1.5 mL of FT azeotrope, at 60 °C; $^b$ Turnover frequencies were determined at the fastest reaction time interval, usually from 6 min to 10 min after reaction had started; $^c$ Hydrogen volume was measured after 20 min, and TON was calculated in the same time zone; $^d$ Reaction without KI; $^e$ TON was measured after 30 min; $^f$ TON was measured after 25 min.
Scheme D.2 (a) Time course of gas evolution during the dehydrogenation of FA with different catalyst amount; (b) Initial TOFs at different catalyst concentrations.

Reaction conditions: 0.1 ~ 5.0 μmol of [RhCp*Cl₂]₂, 500 μmol of KI, 1.5 mL of FT azeotrope, at 60 °C.
Scheme D.3 Time course of gas evolution during the dehydrogenation of FA with different KI amount: 0.8 μmol of [RhCp*Cl$_2$], 0 ~ 500 μmol of KI, 1.5 mL of FT azeotrope, at 60 °C.

Scheme D.4 $^1$H NMR spectra of FA dehydrogenation in neat FA with (upper blue line) and without KI (lower red line): 5.0 μmol of [RhCp*Cl$_2$], 250 μmol of KI, 0.1 mL of FA, 1.0 mL of CDCl$_3$, at room temperature. No Rh-H hydride signal was observed in neat FA.

Scheme D.5 FA dehydrogenation using [RhCp*I₂]₂: 5.0 μmol of [RhCp*I₂]₂, 1 mmol of KI or KCl, 1.5 mL of FT azeotrope, at 60 °C
(a) [RhCp*Cl]_2 in CDCl_3

(b) [RhCp*Cl]_2 + KI in CDCl_3
Scheme D.6 $^1$H NMR spectra of FA dehydrogenation with and without KI: 5.0 μmol of [RhCp*Cl$_2$]$_2$, 250 μmol of KI, 0.1 mL of FT azeotrope, 1.0 mL of CDCl$_3$, room temperature. (a) FA formate proton signal without KI: Con. 18% using TEA as internal standard; (b) FA formate proton signal in presence of KI: Con. 54% using TEA as internal standard; (c) Cp* proton signal in the absence of KI; (d) Cp* proton signal in the presence of KI; (e) Bridging formato ligand proton signal of d; (f) Bridging format ligand proton signal of D; (g) enlargement of Figure 5.8b. The time scale is the same for (a)-(f).
Scheme D.7 (a) & (b): Mass spectra of 1.6 μmol of [RhCp*Cl₂]₂ reacting with 0.2 mL of FT azeotrope (DCOOD vs. HCOOH) in 1.0 mL of methanol at room temperature; (c): Mass spectrum of 1.6 μmol of [RhCp*Cl₂]₂ mixed with 120 μmol of KI in 1.0 mL of methanol; (d): Mass spectrum of 1.6 μmol of [RhCp*Cl₂]₂ reacting with 0.2 mL of FT azeotrope in presence of 120 μmol of KI in 1.0 mL of methanol. All these spectra were obtained at room temperature.
Scheme D.8 (a) FA dehydrogenation with the addition of FA at the end of a reaction: 5.0 μmol of [RhCp*Cl2]2, 1.0 mmol of KI, 1.5 mL of FT azeotrope, at 60 °C. The amount of added FA was roughly based on the evolved gas amount. (b) FA dehydrogenation at prolonged reaction time using [RhCp*Cl2]2 in the presence and absence of KI under the same reaction conditions.
Scheme D.9 $^1$H NMR spectra of the reaction residue after dehydrogenation.

Conditions and procedure: 16.2 μmol of [RhCp*Cl$_2$], 3.0 mmol of KI, 5.0 mL of FT azeotrope, at 60°C, 24 h. After the reaction cooled down, 2 mL of water was added and the organic layer was extracted with 2 mL of dichloromethane. After evaporating the solvent, the residue was submitted to NMR analysis in CDCl$_3$. Comparing the NMR spectra with Figure 5b suggesting that the new rhodium hydride species at -16.22 ppm (q) and -17.74 ppm (q) could possibly be deactivated species.
