This paper studies the impact of a set of managerial characteristics on performance in the top division (Serie A) of the Italian football league during seasons 2000/2001–2009/2010. We employ a bivariate ordered probit model applied to match-level data, which allows for asymmetric effects at home and away matches and in goals scored and conceded. Our set of coach characteristics includes indicators of skill, experience, innate features as well as empathy with the team. We find that some managerial features matter even when we control for club power and past results. Performance is positively correlated with the manager having had experience abroad and with the manager being a former player with the club; but performance is worsened by lack of managerial experience. Other features affect only some particular aspects of performance. In particular, Italian managers are more defensive in home games while older managers are more defensive in away games. Our approach also identifies a negative effect of managerial turnover on defensive performance, an effect which is masked when a more traditional aggregated model is used.

## 1. Introduction

Sports managers are often identified as a key element in explaining team performance. This is corroborated by a number of recent research papers that use sports data to estimate the impact of different manager characteristics on performance; see, for example, Bridgewater *et al* (2011), Hofler and Payne (2006) and Kahane (2005) for analysis of British football, the NBA and the NHL, respectively. They find support for the hypothesis that some manager characteristics such as experience, past success and empathy play an important role to explain in explaining team results.

In this paper, we contribute to this ongoing debate by analysing the causal effect of manager characteristics on match results in the top division (Serie A) of the Italian football league during seasons 2000/2001–2009/2010. The estimation is implemented by a bivariate ordered probit model in which we allow the different features of home and away managers to have a

different impact on the two equations in the model, which account for defensive and attacking performance, respectively.

The use of this econometric framework has at least two important advantages when applied to the estimation of the causal impact of managerial features on performance in football and other contexts. First, it seems plausible to think that the type of manager chosen by a firm is not exogenous to the expected result of the organization, which could result in potential biased estimations when both managers and results are observed simultaneously. Here this problem is circumvented by considering match-level data instead of team season or yearly observations in the case of sport and conventional firms, respectively. The use of high-frequency data not only allows for a more precise estimation of the causal impact but, more importantly, allows the potential simultaneity problem to be addressed because manager characteristics can be considered as exogenous to the result in a particular match after controlling for club status and previous results.

A second important contribution of the paper relates to the disaggregation of different output measures in the organization. More specifically, the proposed specification allows us to

71 explore the impact of different coach characteristics on different  
72 aspects of performance by distinguishing between results at  
73 home and away and goals scored and conceded. This is highly  
74 relevant as the difference between home and away results allows  
75 us to understand how the several managerial characteristics have  
76 their effect on overall performance. Moreover, the distinction  
77 between goals scored and conceded allows us to determine the  
78 relevance of managerial characteristics in two different aspects  
79 of the game that require different abilities. While defence is  
80 typically related to physical training and concentration, attack  
81 requires more skill and inspiration. To our knowledge, this is the  
82 first attempt to analyse how the importance of managerial  
83 characteristics is affected by the external environment and the  
84 degree of skill required for a given task.

85 To preview, we find that manager experience and having  
86 played for the club are important variables to explain team  
87 performance in attack and defence, respectively. This is consis-  
88 tent with the view that experience is helpful to stimulate more  
89 creative skills while empathy with the institution has a more direct  
90 effect on players' attitudes in defence. Nationality and age also  
91 matter for improving defensive skills while other variables  
92 related, for example, to the position where the manager used to  
93 play or his having been active in the previous year are irrelevant.

94 Using the proposed specification, we also study the impact  
95 of managerial turnover on performance. Our estimation results  
96 clearly indicate that replacing a coach has a negative impact on  
97 the defensive skill of the team in away matches. However, this  
98 negative effect is masked when a more traditional econometric  
99 model is used.

100 This paper is organized as follows. The next section relates  
101 our work to the previous literature. In Section 3, we describe  
102 data on managerial characteristics employed in our empirical  
103 work and draw inferences from them regarding typical  
104 circumstances in which dismissals occur in Italy. In Section 4,  
105 we present the estimation of the impact of managerial  
106 characteristics on aggregate performance in the Italian league.  
107 Then, in Section 5 we disaggregate the previous analysis by  
108 estimating the impact of managerial characteristics on goals  
109 scored and conceded in home and away matches. Conclusions  
110 are drawn in Section 6.

## 111 2. Related literature

112 Recent years have witnessed an increasing interest in  
113 analysing the impact of managers' characteristics on firm  
114 performance; see, for example, Kaplan *et al* (2012) and Bloom  
115 and Van Reenen (2007).

116 Although it is generally accepted that managers are key  
117 inputs in understanding the firm's production function, most of  
118 the existing research aims to identify the set of managerial  
119 features that is relevant to augment production output. They  
120 include a broad range of characteristics such as the monitoring  
121 role, resoluteness, persuasiveness and empathy and team-  
122 related skills.

Early work by Mintzerg (1973) identifies the monitoring 123  
role as one of the key characteristics shared by successful 124  
managers. Bridgewater *et al* (2011) pinpoint that successful 125  
managers should be able to play both a teaching role, which is 126  
mostly related to his/her ability, and a credibility role to 127  
convince employees to submerge their egos in the interest of 128  
the firm. They argue that credibility can be achieved by, for 129  
example, reputation and/or expertise. Using information from 130  
British football, they show that these roles are highly 131  
institutional dependent. In particular, the teaching role 132  
becomes more relevant for lower-division teams while man- 133  
agerial experience is especially important to raise the produc- 134  
tivity of top players. The importance of managerial experience 135  
has also been highlighted in other publications related to the 136  
sport industry; see Goodall *et al* (2011) and Hofler and Payne 137  
(2006). Others, like Dawson and Dobson (2002), emphasize 138  
the importance of empathy and team-related skills, finding for 139  
British football that the performance of a club is raised by 140  
being managed by one of its former players. 141

Bolton *et al* (2013) develop a theoretical model that 142  
compares the importance of managerial resoluteness against 143  
communication and listening skills. They conclude that 144  
resoluteness and overconfidence are managerial characteristics 145  
more related to performance than empathy and team-related 146  
skills. However, evidence about this result is mixed in the 147  
literature. For example, Heaton (2002) finds that overconfi- 148  
dence is a negative managerial feature that could result in bad 149  
investment decisions. Results in Gervais *et al* (2011) are 150  
consistent with the view that moderate levels of overconfi- 151  
dence can increase the value of the firms by mitigating moral 152  
hazard and aligning incentives. Malmendier and Tate (2005) 153  
find that overconfident managers are more likely to generate 154  
value-destroying mergers as they show higher investment-cash 155  
flow sensitivity. 156

This paper builds on previous research by studying the 157  
impact of different managerial characteristics on performance. 158  
However, unlike previous research and as explained in the 159  
previous section, the consideration of a bivariate ordered 160  
probit model applied to match-level data in the top division of 161  
the Italian football league allows us to deal with potential 162  
simultaneity problems and to estimate how the impact of 163  
coaches is conditional to the degree of external pressure and 164  
the type of activity the team undertakes. 165

Further, the paper considers a comprehensive set of 166  
managerial characteristics considered in the earlier literature 167  
and estimates the importance of each for firm performance in 168  
the context of football. 169

## 3. Data analysis 170

The data relate to the top Italian football league (Serie A) in 171  
the time span 2000/2001–2009/2010. For the period from 172  
2000/2001 to 2003/2004, 18 clubs participated in Serie A and 173  
there were 20 teams during 2005–2010. We collected data for 174

**Table 1** Descriptive statistics of managers' characteristics

Variable	Obs	Mean	SD	Min	Max
Italian	304	0.94	0.24	0	1
Deputy manager	304	0.05	0.22	0	1
First experience as coach	304	0.11	0.31	0	1
Ex-football player	304	0.85	0.35	0	1
Home-club ex-football player	304	0.20	0.40	0	1
Last home-club ex-football player	304	0.07	0.25	0	1
Ex-football player (goalkeeper)	304	0.03	0.18	0	1
Ex-football player (defender)	304	0.25	0.43	0	1
Ex-football player (midfield)	304	0.53	0.50	0	1
Ex-football player (striker)	304	0.06	0.24	0	1
Experience abroad	304	0.14	0.35	0	1
Activity previous year	304	0.77	0.42	0	1
Age	304	50.52	6.89	36	69

With the only exception of age that is measured in years, all remaining variables are categorical and take only values 0 and 1.

175 3504 matches; for each match, our dataset contains the date of  
 176 the match, the final result, the name of the home and away  
 177 team coaches and their individual characteristics. All data  
 178 come from the official website of *Lega-Calcio*, which  
 179 organized the two highest football leagues in Italy, namely  
 180 Serie A and Serie B, from 1946 to 2010. During the period of  
 181 analysis, Internazionale, Lazio, Milan, Roma and Udinese  
 182 played in Serie A in all ten seasons, while Ancona, Como,  
 183 Treviso, Venezia and Vicenza participated in only one season.  
 184 According to the previous section, information about club  
 185 managers can be split into sets of characteristics that are relevant  
 186 according to the existing literature: experience, empathy with  
 187 the club, ability to teach and resoluteness. However, it must be  
 188 emphasized that the classification of the different observed  
 189 features is not mutually exclusive, and indeed, some features  
 190 belong to more than one group. Table 1 presents some  
 191 descriptive statistics for manager characteristics.

192 As proxies for empathy with the club, we collected  
 193 information about the nationality of the coach, whether he  
 194 had been a player for the same club and whether he had  
 195 previously been an assistant manager with the club. These  
 196 variables could have a positive impact on team performance  
 197 through two channels. First, a manager can take advantage of  
 198 his knowledge of the club because he already knows its  
 199 environment and, probably, its staff. Second, if a manager is  
 200 already known by the supporters, due to share the same  
 201 nationality or past footballer experience, he can have more  
 202 support increasing the chance of success.

203 The second set of individual characteristics refers to  
 204 manager experience. More specifically, we collected informa-  
 205 tion about whether he had had experience abroad, if this was  
 206 his first season as a coach and his age. Manager experience is  
 207 important to deal with the egos of professional footballers and  
 208 convince them to put their effort in favour of the team.

209 Then, we collected information related to the role the  
 210 manager had filled during his career as a player (goalkeeper,  
 211 defender, midfielder and striker). The intuition is that this is

very related to the skills he learned as a player and therefore to  
 his teaching role.

Finally, we also consider whether the manager had been  
 active during the previous year. Not having been a coach in the  
 last year could have an effect on a manager's current  
 knowledge or self-confidence, although, in principle, it is not  
 particularly important in terms of overall experience.

Table 2 shows all the manager dismissals in Serie A during  
 2000–2010. The total number of involuntary removals is 95,  
 with an average of 9.5 events per year. Interestingly, we can  
 observe that poor results are the most frequent causes of  
 manager dismissal (about 89% of cases). All information  
 comes from the official sources of Italian clubs and, as is  
 always the case in such analysis, the real motivation for a  
 dismissal can be grasped from public statistics as well as by  
 using fans club blogs and fanzines. Poor performance of a club  
 is very often the product of a poor relation between staff,  
 manager and players. Furthermore, management disagree-  
 ments may remain latent until a “shock” (a severe defeat,  
 elimination from major competitions, fans objections, etc.)  
 that officially drives to the manager removal. In this sense, it is  
 not observable the real motivation that leads to the change of  
 the coach. Besides, the ranking obtained at the moment of the  
 dismissal is worse than the one in the previous season, giving  
 some motivation of such decision (on average, about four  
 positions down). Furthermore, dismissal coaches exhibit bad  
 results in the last match (mean points equal to 0.44, and the  
 score difference is  $-1.08$ ) and in the last four games (0.61  
 points).

#### 4. Match results model

We estimate an ordered probit model to account for the  
 determination of First Division (Serie A) match results in the  
 Italian league, employing data from games from season  
 2000/2001 to 2009/2010. The first four rounds of matches

**Table 2** Manager dismissals statistics

Variable	Obs	Mean	SD	Min	Max
Quarrel	95	0.02	0.14	0	1
Supporters disagreement	95	0.02	0.14	0	1
Management disagreement	95	0.04	0.20	0	1
Poor results	95	0.89	0.31	0	1
Actual ranking	95	15.44	4.39	2	20
Ranking 1 year before	75	10.72	4.83	1	20
Difference in actual ranking w.r.t. 1 year before	75	4.11	4.88	-12	18
Serie B (previous year)	95	0.17	0.39	0	1
Last result (points)	95	0.44	0.80	0	3
Last score difference	95	-1.08	1.15	-4	2
Last four results (points)	95	0.61	0.45	0	1.75

each season were excluded from the sample because results on  
 teams' previous matches at home and away were used as  
 regressors. A total of 3303 matches remain to be included in  
 the analysis. This is a very large and homogeneous data set  
 that avoids some of the structural changes that potentially can  
 have an impact on the dynamic evolution team performance  
 such as the introduction of the European Champions league in  
 1992 and the Bosman ruling in 1996; see Flores *et al* (2012).  
 In order to analyse the impact of managerial features on  
 results, we adopt the following specification:

$$\begin{aligned}
 y_i^* = & \alpha_1 whh_i + \alpha_2 wha_i + \alpha_3 dhh_i + \alpha_4 dha_i + \alpha_5 wah_i \\
 & + \alpha_6 waa_i + \alpha_7 wai_i + \alpha_8 waa_i \\
 & + \pi_1 m10\_h + \pi_2 m10\_a + \beta tx + e_i
 \end{aligned} \quad (1)$$

where  $e_i$  is a normal error term for the  $i$ th match and the  
 dependent variable,  $y_i^*$  is defined such that

$$y_i = 0 \quad \text{if} \quad y_i^* \leq \delta_1 \quad (2)$$

$$y_i = 1 \quad \text{if} \quad \delta_1 < y_i^* \leq \delta_2 \quad (3)$$

$$y_i = 2 \quad \text{if} \quad y_i^* > \delta_2 \quad (4)$$

The values 0, 1 and 2 indicate whether the home team lost,  
 drew or won the  $i$ th match. The variables  $whh_i$ ,  $wha_i$ ,  $dhh_i$ ,  
 $dha_i$ ,  $wah_i$ ,  $waa_i$ ,  $dah_i$ ,  $daa_i$  are dichotomous dummies that refer  
 to results immediately preceding the  $i$ th match. Specifically,  
 $whh_i$  and  $wha_i$  take a value of one if the home team won its  
 previous home match and its last away match, before match  $i$ ,  
 respectively.  $ah_i$  and  $aa_i$  are defined similarly for the away  
 team. They have value zero otherwise. Variables  $dhh_i$ ,  $dha_i$ ,  
 $dah_i$  and  $daa_i$  are defined in the same way for a draw in the  
 previous match. These variables account for momentum in  
 results and reversion to mean effects.  $m10\_h$  and  $m10\_a$  are  
 the average number of points in the previous ten matches for  
 the home and away teams in that season. In case these previous  
 ten matches have not been played yet, these two variables are  
 substituted by the average number of points in all the previous  
 home and away matches played up to that moment. We  
 consider that these variables can be interpreted both as strength

index variables (for the home and away team) and also as an  
 indicator for the current status of the team. However, we will  
 test the robustness of our results to alternative measures of  
 power.

Our focus is on  $x$  that is a vector including managerial  
 features defined in the previous section: experience abroad  
 active, age, age squared,<sup>1</sup> keeper, defender, midfielder, striker,  
 first experience, previous team player, Italian, previous player,  
 previous vice manager and whether he has replaced a previous  
 coach within the season. In principle, for simplicity we impose  
 the symmetry assumption between the home and away  
 manager effect by defining these variables in differences.  
 Hence, if they take value 1 (-1), it means that the feature is  
 present only in the home (away) manager while if their value  
 is zero it indicates that both managers have an identical value  
 for that feature. This may seem a restrictive assumption and  
 can be criticized on the grounds that the previous literature  
 suggests that supporters may significantly influence the impact  
 of home manager features on results; see Tena and Forrest  
 (2007) and Flores *et al* (2012). However, this restriction will  
 be relaxed in the following section.

Also note that specification (1) is comparable to previous  
 authors who analyse the impact of managerial change, such as  
 Audas *et al* (2002), Tena and Forrest (2007) and Flores *et al*  
 (2012), in the sense that it also allows the estimation of the  
 impact of the new manager on match results in the long run.  
 However, an advantage of the specification here is its  
 simplicity and also that it allows us to control for other  
 managerial features that could potentially be correlated with  
 expected results. Indeed, including these variables in the  
 specification is a way to cope with the potential endogeneity of  
 manager dismissals as this decision is likely correlated with  
 the features of the managers.

We include indicators for past results only if they were  
 significant at the 5% level. This leaves only one past result

<sup>1</sup>Age and Age<sup>2</sup> are included in order to take into account nonlinear  
 effects. The rationale is that growing older has a positive impact on his  
 team's results. But, at some point in time any further increase in the age  
 may lead to a reduction in ability and performance. However, dropping the  
 square term we obtain the same results.

**Table 3** Random effects ordered probit regression: (a) estimated parameters and (b) marginal effects on match results evaluated at averaged values

	(a)			(b) On home win			(b) On draw		
	Coef.	Se	z	dy/dx	Se	z	dy/dx	Se	z
Home team won its last away match	0.095	0.043	2.21	0.035	0.015	2.21	-0.007	0.003	2.18

Notes the residuals are clustered at teams' pair level.

<sup>a</sup> Statistical test for the whole model specification.

318 indicator: “home team won its last away match”. In addition,  
 319 in order to allow for the fact that the error term in expression (1)  
 320 is not homoscedastic, we consider random effects to account  
 321 for the potential heterogeneity that depends on each of the  
 322 home and away team pairs, 70 individual effects in total. We do  
 323 not estimate fixed effects in the ordered probit model due to the  
 324 well-known incidental parameter problem, which can cause  
 325 difficulties if the manager variables fail to be exogenous. The  
 326 solution of including past results would not be valid in this case  
 327 if the same manager had been in place for the preceding ten  
 328 matches, as well as for the current match. The past results  
 329 variables are, therefore, likely to absorb some of the influence  
 330 of the coach variables. This could potentially introduce  
 331 downward bias in the estimated parameters. However, it is  
 332 important to note that the correlation matrices between the  
 333 variables in the model (see “Appendix”) indicate that the  
 334 correlation of manager features with past results is lower than  
 335 10% in all cases. Therefore, in principle, it seems unlikely that  
 336 past results absorb the influence of the coach variables.  
 337 We present in Table 3 the estimated parameters and  
 338 marginal effects from the ordered probit estimation for a home  
 339 win and a draw. The fact that previous results of the home and  
 340 away team exert no significant influence on the current result  
 341 could be considered as puzzling at the first sight. The reason for  
 342 this is that in the regression we are also controlling for the  
 343 impact of the last ten matches. Indeed, if the two variables

accounting for the influence of the last ten matches are dropped 344  
 from the regression, the impact of previous results by the home 345  
 team becomes significant and positive. Hence, average points 346  
 in the last ten matches, intended to capture differences in power 347  
 between “weak” and “strong” teams, have a strong predictive 348  
 power in accounting for the pattern of results. 349  
 Coefficients on our focus variables are significant at the 5% 350  
 level only for experience abroad, first experience and previous 351  
 player with the club. Results are consistent with our expecta- 352  
 tions about the importance of experience and the manager’s 353  
 identification with fans, which could make him more prone to 354  
 make a greater effort to increase team performance. Moreover, 355  
 we can suppose that former club players have a lot of (formal 356  
 and informal) information about their own club, probably 357  
 collected during their previous, and they are able to use such 358  
 knowledge to improve the results of the club. Therefore, the 359  
 human capital of managers seems to play a role in explaining 360  
 differences in a club’s performance. Interestingly, an invol- 361  
 untary managerial change within the season has a negative but 362  
 not significant impact on performance. 363  
 Although our indicators of team power are significant in the 364  
 regression, there are, of course, alternative ways of generating 365  
 a proxy for club strength. In a study focussing on the issue of 366  
 competitive balance, Koning (2000) took a very direct 367  
 approach. The covariates in his ordered probit match results 368  
 model were dummy variables representing each club which 369

370 had taken part in the Netherlands Premier League. Here, as a  
 371 robustness exercise, we re-estimate our model, but instead of  
 372 including the two variables which capture information from  
 373 the last ten matches we allow for individual effects for each  
 374 club at home and away. This amounts to the inclusion of 70  
 375 new parameters to be estimated. This specification is not a  
 376 parsimonious specification, and it restricts the power of each  
 377 team to be similar across different seasons. In spite of this  
 378 restriction, we could still find similar impacts for managers’  
 379 characteristics and we can also conclude that a new manager  
 380 exerts a negative but not significant influence on results, and  
 381 the impact on home win (draw) is  $-0.025$  ( $0.005$ ) with  $z$ -  
 382 statistics  $1.73$  ( $1.73$ ).

383 Regarding the impact of a managerial turnover, it is also  
 384 relevant to compare our results with a recent paper by De Paola  
 385 and Scoppa (2012) also for the Italian league. These authors  
 386 present a highly very insightful and interesting discussion about  
 387 the potential endogeneity problem and its influence on the  
 388 analysis of managerial replacements. They argue that apart  
 389 from the endogeneity problem due to mean reversion that can  
 390 be controlled by using lagged match results, there is some  
 391 remaining endogeneity that derives from the fact that coaches  
 392 are not fired randomly throughout the season and that may  
 393 depend on the perceived improvement that may emerge. They  
 394 focused on this form of endogeneity and addressed it by  
 395 employing an instrument that is correlated with the decision of  
 396 firing a coach but uncorrelated with the error term of the model.  
 397 They argued that the variable “remaining matches” in that  
 398 season fulfils these two properties of a valid instrument.  
 399 Although this variable is an interesting way to deal with this  
 400 problem, note that we use a more extended sample and, at least  
 401 for our dataset, the probability of dismissal is uncorrelated with  
 402 round. Figure 1 shows the distribution of dismissals by round,  
 403 suggesting that their distribution is more or less uniform except  
 404 at the very beginning and end of the season where the  
 405 proportion of dismissals are particularly low. According to this  
 406 result, it makes sense to treat the potential endogeneity problem  
 407 as we do in Eq. (1) by including lagged results, to account for

Figure 1 Average number of managerial dismissals by round. Seasons 2000/2001 to 2009/2010.

mean reversion, and features of the different managers that 408  
 explain the probability of coach dismissals. 409

In spite of using different econometric specifications, our 410  
 results are comparable with those in De Paola and Scoppa 411  
 (2012): a managerial change has no impact on match results. 412  
 Moreover, this result also holds when we restrict our sample to 413  
 the five seasons considered by De Paola and Scoppa (2012), 414  
 the estimated impact of a new manager on home victory 415  
 (draw) is  $-0.021$  ( $0.004$ ) with associated  $z$ -statistic of  $-1.06$  416  
 ( $1.06$ ). 417

### 5. Extending the basic model 418

Model (1) in the previous section is based on two important 419  
 restrictions about the impact of managers on results, namely 420  
 (1) the impact of home and away managers is symmetric; (2) 421  
 managers have a similar effect on goals scored and goals 422  
 conceded. Relaxing these assumptions is important for under- 423  
 standing the reasons why the various managerial characteris- 424  
 tics are important. 425

We adopt the following bivariate ordered probit model 426

$$g_{_h}^* = \gamma_{11}g_{_hh_i} + \gamma_{12}g_{_ha_i} + \pi_{11}m10_h + \pi_{21}m10_a + \beta'_{11}h_{_x} + \beta'_{12}a_{_x} + e_{1,i} \quad (5)$$

$$g_{_a}^* = \gamma_{21}g_{_ah_i} + \gamma_{22}g_{_aa_i} + \pi_{21}m10_h + \pi_{22}m10_a + \beta'_{21}h_{_x} + \beta'_{22}a_{_x} + e_{2,i} \quad (6)$$

where  $e_{1,i}$  and  $e_{2,i}$  are two normalized error terms that could be 430  
 contemporaneously correlated,  $g_{_h}^*$  and  $g_{_a}^*$  are associated 432  
 with the observed number of goals (0 for no goals, 1 for one 433  
 goal and 2 for more than one goal) scored by the home ( $g_{_h}$ ) 434  
 and away ( $g_{_a}$ ) teams, respectively, according to 435

$$g_{_h} = \begin{cases} 0 & \text{if } g_{_h}^* \leq c_{11} \\ 1 & \text{if } c_{11} < g_{_h}^* \leq c_{12} \\ 2 & \text{if } c_{13} < g_{_h}^* \end{cases} \quad g_{_a} = \begin{cases} 0 & \text{if } g_{_a}^* \leq c_{21} \\ 1 & \text{if } c_{21} < g_{_a}^* \leq c_{22} \\ 2 & \text{if } c_{23} < g_{_a}^* \end{cases} \quad (7)$$

Variables  $g_{_hh_i}$ ,  $g_{_ha_i}$ ,  $g_{_ah_i}$  and  $g_{_aa_i}$  are the number of 437  
 goals scored and conceded by the home and away teams, 439  
 respectively, in their previous matches;  $h_{_x}$  and  $a_{_x}$  include 440  
 the same managerial features considered in model (1) from the 441  
 previous section, but defined for the home and away managers, 442  
 respectively. All these variables are dichotomous and take 443  
 value 1 if the feature is present in the manager and 0 otherwise 444  
 except for age that indicates the age of the manager in years. 445

Note that equations (5), (6) and (7) constitute a seemingly 446  
 unrelated specification. The identification conditions as well 447  
 as the estimation of such models is discussed by Sajaia (2008). 448

A well-known problem of multinomial probit models is 449  
 that, as the number of dimensions increases, many standard 450

<sup>a</sup> Statistical test for the whole model specification; <sup>b</sup> LR test of independent equations.

451 estimation procedures of random effects suffer from numerical  
 452 stability, convergence and precision problems. For  
 453 example, Grilli and Rampichini (2003) indicate that the time  
 454 required for the estimation increases rapidly with the  
 455 complexity of the model, even when using flexible packages  
 456 such as GLLAMM. Similarly, we also experienced conver-  
 457 gence problems in the estimation of the bi-ordered probit  
 458 model with random effects, and we decided to show the  
 459 results for a model with no random effects, but with standard  
 460 errors corrected for clustering for each pair of home and away  
 461 teams.

Tables 4 and 5 report the estimated parameters and the  
 marginal impacts of the variables in the model for home and  
 away goals. Results in the table indicate how the different  
 managerial features affect the defensive and offensive skills of  
 the team. When the manager is inexperienced, he has a  
 negative impact on the numbers of goals that the team scores  
 both at home and away. In principle, this is consistent with the  
 view that a less experienced manager will have less ability to  
 stimulate the creative team skills with new tactics, as he has no  
 experience in its implementation. On the other hand, a  
 manager who has been a previous player with the club

473 significantly improves the defensive skill of the team by  
474 conceding fewer goals to his rivals.

475 Results in this table allow us to discover some effects of  
476 managerial features that are masked in an aggregate analysis  
477 because it does not distinguish between performances at home  
478 and away as well as in defence and attack. For example,  
479 experience abroad matters particularly in away matches. It is  
480 also worthy of note that none of the position variables is  
481 significant relative to the excluded category: non-player. Being  
482 active as a manager in the previous year is also insignificant  
483 which suggests that it is the whole experience as a manager that  
484 matters rather than what he has done in the recent past.

485 First experience has a negative impact, as expected, that is  
486 more important in home matches. These are situations in  
487 which the home manager is tested by his own supporters that  
488 could be deemed to be more reluctant to accept an inexperience  
489 manager.

490 Finally, although it has been found in the previous section  
491 that being an Italian manager does not have any significant  
492 effect on match results, the estimation here shows that a home  
493 Italian manager significantly reduces the probability of scoring  
494 home goals. This is, to our knowledge, the first empirical proof  
495 for the stereotype about the defensive orientation of Italian  
496 managers.

**Table 6** Robustness checks for the effect of a new manager on results

<i>dy/dx</i>	<i>Symmetric effect at home and away</i>		<i>Asymmetric effect at home &amp; away</i>

Home win/draw random effects ordered probit model.

AIC denotes the Akaike criterion; test (I) represents the test on the coefficients under the null hypothesis that the difference between the coefficients associated with manager turnover in models (C) and (A) is zero; test (II) represents the test on the coefficients under the null hypothesis that the difference between the coefficients associated with manager turnovers in models (C) and (B) is zero. (I) The Symmetric effect does not distinguish between the effect of the new home and away managers while this distinction is considered for the Asymmetric effect case and it is denoted by (h) and (a) respectively. \*, \*\* and \*\*\* indicate significance at the 10, 5 and 1% levels, respectively.

497 One potential problem with the estimations reported in  
498 Tables 4 and 5 is the fact that it includes too many covariates and  
499 some of them could be spuriously significant by chance. In order  
500 to deal with this multiplicity issue suggested by the referee, in an  
501 additional experiment we have followed an iterative stepwise  
502 procedure in models (5) and (6) dropping in each step the less  
503 significant variable until all of them are significant at the 5%  
504 level. The estimates of the most significant parameters show  
505 similar signs and even a similar magnitude.

506 Some special attention must be paid to the effect of  
507 managerial change on performance. Although it has been  
508 shown that a new manager has a non-significant result using  
509 the aggregate model in the previous section, this analysis finds  
510 that a managerial replacement increases the probability of  
511 achieving goals at away matches.

512 Estimating the impact of a new manager has received great  
513 attention in the literature on sports economics (Audas *et al.*,  
514 1999, 2002; Tena and Forrest 2007; Flores *et al.*, 2012). In their  
515 papers, Audas *et al.* (1999, 2002) analyse this issue in an ordered  
516 probit model for match outcome results, which they use to  
517 estimate the causal effect of recent managerial changes repre-  
518 sented by a series of dummy variables. These models include  
519 information on past results in order to control for mean reversion.

520 This approach has been followed in more recent articles but  
521 including some modifications in the estimation procedures.  
522 Although an exhaustive comparison of all the existing  
523 literature is out of the scope of this paper, it may be noted  
524 that Tena and Forrest (2007) and Flores *et al.* (2012) allowed  
525 the new manager to have a different impact in home and away  
526 matches for the Spanish and the Argentinean league, respec-  
527 tively, and found that this effect is asymmetric and signifi-  
528 cantly more negative at away matches.

529 Table 6 compares the effect of a managerial change in the  
530 Italian league using an ordered probit specification with  
531 different set of variables used as regressors. Namely, the

inclusion of past results, to control for a possible mean 532  
reverting effect, manager characteristics, to deal with the 533  
potential endogeneity problem of coach substitution, different 534  
dummy variables for home and away managers to control for 535  
the asymmetric effect found in the literature. It can be 536  
observed that estimation results are not significantly different 537  
under the different econometric specifications once we control 538  
for past results what is a common practice in the existing 539  
literature. According to these results, we can conclude that, 540  
regardless the econometric specification chosen for the 541  
analysis, changing a manager has no effect on performance 542  
at the 5% significance level. 543

544 However, results become sharper once we disaggregate  
545 between performance in attack and defence using a bivariate  
546 ordered probit model. Table 7 shows the effect of a new  
547 manager under different assumptions in this model. It can be  
548 seen that the use of this disaggregate analysis allows us to  
549 conclude that, regardless of the covariates considered in the  
550 econometric specification, the new manager significantly  
551 worsens team defensive performance at away matches.

552 In an additional exercise, we also appraise the relevance of  
553 the model specification and managerial variables in a  
554 forecasting exercise. In particular, using the sample  
555 2000/2001–2007/2008, we estimate ordered probit models  
556 and bivariate ordered probit models, with and without  
557 managerial variables that are significant at the 5% level. The  
558 different models are evaluated in terms of their ability to  
559 forecast home victory, draw and away victory in seasons  
560 2008/2009 and 2009/2010, compared to a naive benchmark  
561 specification which, based on the estimation sample, gives  
562 probability 0.45, 0.30 and 0.25 to home win, draw and away  
563 win, respectively. To do this, we apply the logarithmic scoring  
564 rule (LSR) suggested by Bickel (2007). In order to compare  
565 the predictive quality of two different forecasting methods, we  
566 adapt the Wald-type statistic given by Boero *et al.* (2011); see,

**Table 7** Robustness checks for the effect of a new manager on results

dy/dx	Symmetric effect at home and away				Asymmetric effect at home and away

Home win/draw bivariate ordered probit model for attack and defence.

AIC denotes the Akaike criterion; HGE and AGE stand for home goals equation and away goals equation, respectively; tests (Ia) and (Ib) represent the test on the coefficients under the null hypothesis that the difference between the coefficients associated with manager turnovers in models (C) and (A) is zero for home team goals and away team goals, respectively; tests (IIa) and (IIb) represent the test on the coefficients under the null hypothesis that the difference between the coefficients associated with manager turnovers in models (C) and (B) is zero for home team goals and away team goals, respectively. \*, \*\* and \*\*\* indicate significance at the 10, 5 and 1% levels, respectively; (a) denotes the Akaike criterion.

**Table 8** Logarithmic scoring rules (LSR) and significance tests

	Random effects ordered probit model (1)	Bivariate ordered probit (2)	Test between (1) and (2)
(A) Past results	1.019	1.024	$ t  = 1.12$
(B) Including statistical significant managers features	1.013	1.023	$ t  = 0.20$
(C) Including past results and all managers features	1.016	1.017	$ t  = 0.08$
(D) Control test	1.066	1.066	
-Test (A-D)	$ t  = 2.27$ **	$ t  = 2.20$ **	
-Test (B-D)	$ t  = 2.39$ **	$ t  = 2.17$ **	
-Test (C-D)	$ t  = 2.06$ **	$ t  = 2.29$ **	
-Test (A-B)	$ t  = 0.25$	$ t  = 0.71$	
-Test (A-C)	$ t  = 0.76$	$ t  = 0.18$	
-Test (B-C)	$ t  = 1.02$	$ t  = 0.85$	

\*, \*\*, \*\*\* indicate significance at the 10, 5 and 1% levels respectively.

567 also, Giacomini and White (2006). Table 8 shows the results  
568 of this exercise. In this comparison, it should be noted that a  
569 general result in econometrics is that adopting a parsimonious  
570 models usually leads to a better forecast as the sampling  
571 variation in parameter estimates may adversely affect predic-  
572 tion; see, for example, Clements and Hendry (1998). It can be  
573 seen that all specifications significantly improve the forecast  
574 performance of the benchmark, and, most importantly, more  
575 sophisticated models, such as the bivariate ordered probit  
576 model with managerial variables, do not forecast significantly  
577 worse than much simpler specifications that include only

information on past results. This result provides an additional 578  
argument for the use of more sophisticated econometric 579  
specifications, as they are more informative than their more 580  
parsimonious counterparts. 581

## 6. Concluding remarks 582

This paper has analysed the importance for performance of 583  
different managerial features. Sports economics offers a fertile 584  
ground for this estimation given that the relevant information 585

586 used in the analysis is unambiguously defined and can be  
587 freely obtained from the media.

588 We study this issue in the context of Italian football, finding  
589 that some managerial features have a significant influence on  
590 results even when we account for indicators of team strength  
591 and recent results. Variables related to experience turn out to  
592 have a significant positive impact on performance. The  
593 variable “previous team player” positively influences team  
594 results. We also find that cultural values are also important. In  
595 particular, being an Italian manager reduces the probability of  
596 scoring goals in at home games.

597 The econometric specification used in the analysis is demon-  
598 strated to be useful in order to estimate the impact on results of  
599 involuntary managerial change in a model that controls for both  
600 past results and managerial features that are correlated with the  
601 decision to change a manager. We find that the consideration of  
602 different models for performance in attack and defence is relevant  
603 to study the impact of a managerial change as the total effect can  
604 be masked in the aggregate counterpart.

605 *Acknowledgements*—We are very grateful to two anonymous referees for  
606 incisive suggestions and to Bruno Atzori for excellent research assistance.
