Type of Article: Review

Keywords: adaptive governance; biodiversity conservation; governance; ecosystem transformation; environmental governance; novel ecosystems
Abstract

Meeting conservation objectives in an era of global environmental change has precipitated debate about where and how to intervene. Ecological and social values of novel ecosystems are particularly contested. Governance has a role to play, but this role is underexplored. Here, we critically review the novel ecosystems literature to identify challenges that fall within the realm of governance. Using a conceptual framework for analysing adaptive governance, we consider how governance could help address five challenges. Specifically, we argue that reforming governance can support the re-framing of policy objectives for ecosystems where transformation is likely, and in doing so, it could highlight the tensions between the emergence of novel ecosystems on the one hand and cultural expectations about how ecosystems should look on the other. We discuss the influence of power, authority and administrative competence on conservation efforts in times of environmental change. We consider how buffering can address translational mismatch between conventional conservation policy and modern ecological reality. This review provides insights into how governance reform could enable more adaptive responses to transformative changes, such as novel ecosystems, while remaining committed to achieving conservation outcomes. Indeed, at their best, adaptive responses would encompass the reality of ecological transformation while being sympathetic to concerns about undesirable outcomes. Connections between researchers in the fields of governance, ecology and conservation could help to achieve these twin aims. We provide examples of governance and policy-making techniques that can support context-specific governance reform that supports more effective conservation in the Anthropocene.
Introduction

In what has been dubbed ‘the Anthropocene’ epoch (Steffen et al. 2007), humans are having unprecedented impacts on natural systems. The rapid pace of environmental change has prompted debate about how conservation goals and management should change, particularly for hybrid and novel ecosystems (NE) (Hobbs et al. 2014; Truitt et al. 2015). Hybrid ecosystems occur in highly modified landscapes where key attributes or functions (e.g. nutrient load, hydrology) are the same but most of the species have changed compared with historical ecosystems (Hobbs et al. 2009). The emergence of NE – where species changes are accompanied by altered function and interactions – are likely in many areas across the globe, due to the intensity and pace of drivers of ecosystem decline (Hobbs et al. 2014). At the crux of the debate prompted by NE is the question of whether such changes are reversible and if so, how conservation and restoration policies and practices should be reformed to deal with these transformative changes (Murcia et al. 2014; Perring et al. 2015; Truitt et al. 2015). Accepting irreversible changes and new management objectives challenges a fundamental tenant underpinning ecosystem restoration and biodiversity conservation, i.e. that of anchoring management goals to historical baselines (Hobbs et al. 2014). Consequently there is some palpable anxiety in NE literature, with concerns including displacement of conventional management approaches, whether ‘giving in’ to NE means ‘giving up’, and whether the public will accept and value NE (Murcia et al. 2014; Standish et al. 2013).

These concerns raise normative questions about decision-making, responsibility, and social desirability that cannot be answered by collecting more biophysical and
These questions are in the realm of governance. Governance provides a link between social and ecological systems, and for better or worse influences the trajectory of these systems (Chaffin et al., 2014). The importance of understanding and reforming governance has been alluded to in this debate; however, so far the NE literature has not engaged extensively with the governance literature. Where it has, the focus has largely been on how governance provides a barrier to sensible management of NE, or on emphasising how social barriers (e.g. community perceptions and cultural expectations) impede progress (Hobbs et al. 2009; Standish et al. 2013; Truitt et al. 2015). The aim of this article is to review the specific aspects of governance that have been discussed in the NE literature, and to identify focal points for governance reform if deliberately pursuing, identifying and managing NE is an accepted conservation option. After a brief discussion of governance in the context of NE, we use a conceptual framework for analysing adaptive governance to evaluate the NE literature. While acknowledging that the pace of governance reform is generally slow to react to the speed or magnitude of many of social and ecological drivers of environmental change, we use insights from this review to develop guidance for a reform agenda that can help build competence for more effectively responding to such transformative changes.

2 Governance and environmental change

Governance is described variously in the literature as both a system and a process. Broadly, governance refers to a system of social coordination for resolving common challenges. More specifically, it refers to the interactions between state and non-
state actors undertaken to address these challenges, and includes the institutions and principles mediating those interactions (Armitage et al. 2009; Kooiman, 2003; Lange et al., 2013). Institutions are the rules, strategies and norms that guide individual and organisational behaviour (Ostrom 2005). They can be formal (e.g. laws, constitutions, policies) or informal (e.g. norms, strategies, codes of conduct). Governance occurs at multiple spatial scales and levels (e.g. local, regional, state, national); however, it is distinct from management in that governance sets the vision and direction (e.g. through policy), whereas management operationalises the vision (Folke et al., 2005). Governance is often categorised into different modes, which vary in terms of political processes, policy content, and institutional structures (Lange et al., 2013).

The notion of “fit” is a useful way to link these general ideas about governance to the specific issue of NE. Fit refers to the need for governance to be tailored to the environmental issue being addressed. When governance is fit-for-purpose, it can provide the framework for making difficult decisions discussed in the NE literature (e.g. providing the authority to manage for NE under certain conditions) (Hobbs et al. 2014; Truitt et al. 2015). Examples of poor fit are varied but can include a lack of capacity for dealing with the right drivers, a lack of competence (e.g. skills or resources) for dealing with social or ecological drivers, a failure to manage political influences or insufficient authority to deal with drivers, or an agenda that poorly defines the problem or excludes key players (Clement et al. 2016a; Young 2008). This alignment between the problem and governance matters because governance influences how decisions are made about NE, who makes those decisions, who is
responsible for acting, and how and why managers intervene. Importantly, governance provides a forum for considering scientific data about transforming ecosystems, but it is much broader than that. It provides a means for considering competing and often conflicting values alongside scientific knowledge to establish overarching objectives. From a practical perspective, it also determines where (and how much) resources are invested in managing ecosystems, and whether that money is invested in more conventional or novel approaches.

2.1 Approach to review

We critically reviewed the NE literature to identify “sticking points” or barriers to deciding if, when, where, and how to manage NE for conservation outcomes that authors associated with governance. Papers for the review were obtained from searches for novel ecosystems and related terms (e.g. hybrid ecosystems, constructed ecologies) in search aggregators, which index metadata from a wide scope academic publishers and databases of articles published between 2000 and 2016 (e.g. Web of Science, Scopus, JSTOR, Science Direct). We uncovered 118 articles, which were then screened for discussion relating to governance aspects of NE, with irrelevant articles being removed from the review, leaving 49 articles. Further screening was then undertaken to remove articles that only briefly mentioned governance and social aspects of NE to arrive at the 15 articles included here.

To organise the review and provide insight into the areas where governance may need to be reformed to enable more effective action with respect to NE, we applied
an original framework developed by Clement et al. (2016a). This framework identifies the aspects of governance that are important for building general and adaptive capacity for conserving biodiversity, as identified in the adaptive governance literature (e.g. Armitage and Plummer 2010; Brunner 2010; Chaffin et al. 2014) and the broader institutional literature (e.g. Meier and O’Toole 2008; Scott 2014). This focus on adaptive governance was chosen because, while traditional governance systems tend to adopt a rigid, rules-based approach to decision-making, adaptive governance offers alternative principles for decision-making better equipped to cope with uncertainty and complexity in ecosystem management through a more experimental, learning-driven approach (Chaffin et al. 2014).

Acknowledging that ideals of adaptive governance are difficult to achieve, the framework explicitly considers adaptive capacity alongside practical constraints limiting adaptation (e.g. budgets, legal constraints, accountability mechanisms) (Clement et al. 2016a). The framework attends to adaptive capacity, or the ability of institutions to withstand and respond to change (Armitage and Plummer 2010); but equally highlights the importance of general capacity, or the ability to identify and solve problems and deploy knowledge and skills (Virji et al. 2012).

The framework can be applied to specific cases to determine where governance is and is not fit-for-purpose, but here it is used as an analytical tool to review where the literature has identified poor fit (Section 3), identify areas that have been neglected in the literature (Section 4), and then develop guidance on techniques that can be used to help guide governance reform in particular places.
The benefit of a diagnostic approach is that it focuses analysis on the governance aspects most salient for dealing with an environmental problem, in this case aspects of adaptive governance salient to the emergence of NE. The conceptual framework is organised as four broad categories:

1. **Problem and players**, which has two components: how the problem is framed including who is causing and could be involved in solving the problem, and the *culture and norms* that drive behaviour.

2. **Politics**, which consists of two components: how institutions interact *(interplay)* and the *power and authority* influencing action.

3. **Competence** includes three components: basic skills and resources for action *(administrative competence), cooperation, and learning processes.*

4. **Capacity**, which encompasses essential aspects for adaptive capacity in three components: *leadership, buffering, and self-organising.*

Every component of this framework is built on the notion of fit discussed earlier. The framework is fully described in Clement *et al.* (2016a) and summarised in more detail in the supplementary material. In this case, the focus was on the areas of poor fit identified by authors in the NE literature, with the framework providing a way to organise ideas in the concerns in the NE literature. All information relating to governance from the articles were organised and categorised, using a priori codes from the framework and a second level of analysis to cluster the data and identify themes (Creswell 2013).

3 **Governance challenges for managing novel ecosystems**
Of the 10 components in the framework, only five components (framing, culture and norms, administrative competence, power and authority, and buffering) emerged as most prevalent in this literature, which are discussed here as “sticking points” (see also supplementary material). These are not the only barriers to dealing with NE and may in fact be perceived, rather than actual, barriers. Regarding perception, attention to these five components of governance, whether through further research or targeted, context-specific governance reform, could advance the debate about NE and enable more effective adaptation in landscapes where drivers of environmental change are intense and restoration to historical baselines has become a challenging, if not impossible, endeavour. After summarising the governance challenges presented in the NE literature, we draw attention to components of the framework that have been neglected in this literature, bringing in insights from the governance literature to discuss how governance reforms and interventions could provide capacity to proactively meet the challenges of NE intervention (Section 4).

### 3.1 Framing

Framing refers to how biodiversity and conservation are conceptualised in a particular place, how environmental problems are defined and consideration of their causes. Framing drives the rationale for conservation, determines who is involved, and what solutions and/or actions are deemed acceptable (Clement et al. 2016a).

Authors argue that current legal and policy frameworks are a poor fit for accommodating novel ecological challenges and solutions. This misfit includes policy and legal barriers to managing and restoring ecosystems in novel ways (Collier 2015;
Hobbs et al. 2009), and failure to consider the value of NE or functional equivalence in current approaches (Starzomski 2013). The lack of clear definition and diverse ways of viewing the problem and potential management actions are also said to impede progress for addressing the challenges of novel and hybrid ecosystems (Morse et al. 2014; Murcia et al. 2014; Truitt et al. 2015).

Although understandings of “natural” vary across countries, biodiversity conservation is still largely framed as the protection of rare and/or culturally valued assets (e.g. species, habitats) from threats and success is anchored to culturally relevant baselines. These tendencies have been criticised for focusing too much on outputs (e.g. number of trees planted) and neglecting outcomes (e.g. ecosystem processes), leading organisations to do the same and contributing to policy failure (Bennett et al. 2009). The critique is even more relevant as ecosystems transform, as new types of ecosystems will require new ways of framing the problem of biodiversity decline, defining what conservation means, and the portfolio of possible solutions. This re-framing will require a clear and practical definition of NE (Hobbs et al. 2014). Any re-framing must also be balanced against potential unintended consequences and deterioration of standards (Graham et al. 2014; Standish et al. 2013).

### 3.2 Culture and Norms

Culture and norms influence behaviour through shared perceptions of what is proper and improper behaviour in a particular situation (Ostrom 2005), thus having consequences for what is deemed acceptable in conservation and restoration. This
component refers not just to societal norms, but also the culture and norms of scientists, practitioners, and the organisations responsible for conservation (Clement et al. 2016a).

Framing (and re-framing) of conservation is part science and part culture, but it is the cultural aspects that have received much attention in the NE literature. One of the recurring concerns about NE is whether the public will de-value them, or simply value them because they are novel (Standish et al. 2013). In the NE literature, this concern is often expressed as a need to overcome community resistance to the idea of NE and dispel idealism about nature (Graham et al. 2014; Hobbs et al. 2009). This discussion is often couched in terms of cultural values toward nativeness and exoticism and cultural values about historic fidelity and ecological integrity (Manning et al. 2009). Authors also refer to sentimentality about historic ecosystems and static views of ecosystems as particular assemblages in particular places in discussing cultural barriers (Hobbs et al. 2009; Hobbs 2016; Light et al. 2013). This sentimentality is not limited to the public, academics and practitioners are also thought to have enduring preferences for conventional management actions (e.g. protected areas, restoration to baseline, protecting specific species), which can be a barrier to accepting novel or more interventionist management options (Hagerman and Satterfield 2014).

Fostering “new norms” is said to be doubly challenging because of potentially dangerous perverse consequences of accepting change (Graham et al. 2014; Murcia et al. 2014; Standish et al. 2013). There are fears discussed in the NE literature that
changing cultural norms about what is worth protecting will be used in a political context to support degrading actions (Murcia et al. 2014). Ultimately this fear reflects that the emergence of NE and hybrid systems raise value-laden questions about conservation that require broad public dialogue (Hobbs et al. 2014; Hobbs 2016), yet social values in relation to NE are largely unknown (Collier 2015).

3.3 Power and authority

Governance establishes institutions and policies; empowers individuals and organisations to act; and allocates roles, responsibilities, and authority. Authority confers formal power to act and can be codified in law, but it may also be more informal and arise from differing levels of political influence, money, or other resources. The framework used here draws attention the fact that while power can block governance reform and effective action, it can also empower actors and enable collective action (Clement et al. 2016a).

Power and authority are rarely discussed in those explicit terms in the NE literature, but there are concerns that intentional management of NE legitimises human control over the environment, potentially empowering actors to degrade ecosystems under the guise of conservation (Graham et al. 2014; Murcia et al. 2014; Standish et al. 2013). There are also practical legal challenges, with authority tied to formal legal frameworks and land tenure constraining action (Hulvey et al. 2013). New approaches will also require reallocation of rights and responsibilities and setting new procedures for practice (Richardson and Lefroy 2016).
3.4 Administrative competence

Administrative competence refers to the basic skills and resources required to conserve biodiversity, and it is this component of the framework where the pragmatic concerns in the NE literature about cost, technical knowledge, and skills are accommodated. Translating biodiversity conservation from paper to practice requires knowledge, capacity to manage in general as well as to adapt, and human and financial resources commensurate with the scale of the problem (Clement et al. 2016a). Many of the debates in the NE literature relate to balancing resource constraints against what is and is not feasible in practical terms.

The feasibility of managing for historical, hybrid, or NE is determined in part by budget constraints and scale of interventions. Authors call attention to the need for new practices and technical knowledge about how to manage NE and the efficacy of differing management actions (Collier 2015; Hobbs et al. 2014; Seastedt et al. 2008). Criteria including reference points, baselines, and bio- and environmental indicators as metrics of change are needed to standardise the use of the NE concept for management and policy decision-making (Morse et al. 2014; Truitt et al. 2015). This is both a scientific and a normative challenge. While anchoring management objectives to historical baselines may still be theoretically possible in some landscapes; it may require unrealistic resource investment, calling into question not just technical feasibility but also financial viability of projects and whether it is an acceptable use of resources (Hobbs et al. 2014; Hulvey et al. 2013). This prospect raises questions about costs, benefits, and realistic objectives for transforming landscapes. A bigger issue here is the mismatch between changing social and
ecological context and current approaches to conservation (Collier 2015; Seastedt et al. 2008).

3.5 Buffering

Conservation in the Anthropocene means adapting conservation practices to deal with transforming ecosystems and increasing human pressure on the environment. Buffering is about directing responses to the right drivers and being able to manage both internal and external influences (both social and ecological) on an ecosystem as well as the organisations managing those ecosystems. It is key aspect of social-ecological resilience, requiring managers to recognise thresholds and disturbances, respond adequately, and cope with uncertainty to buffer human influence on ecosystems (Boyd and Folke 2011). Effective buffering is a balancing act: conservation organisations must be open to their environment but some management of political and other external pressures is required to effectively manage ecosystems and respond to drivers of decline (Clement et al. 2016a; Meier and O’Toole 2008).

Questions about how to adjust strategies in light of the transformative changes seen in novel and hybrid ecosystems are contentious and debated on both scientific and philosophical grounds. For example, concerns have been raised about defining NE, predicting ecological responses to rapid change, the irreversibility of change, whether NE are inevitable and where to manage for them, and whether doing so gives licence to degrading actions (Murcia et al. 2014; Perring et al. 2015; Truitt et al. 2015). All of these are buffering questions because they are about knowing how to
respond adequately to environmental changes at the right times and doing so in the midst of external pressures and under conditions of significant uncertainty.

A considerable issue related to all of the above links buffering to framing. When legislative mandate and formal authority is tied to managing for specific listed species and ecosystems, the ability to buffer, i.e. target the larger-scale drivers of ecosystem decline, is constrained. Narrow framing also means many biodiversity assets and ecosystem processes are not protected by legislation but may be valued nonetheless (Hobbs et al. 2009; Seabrook et al. 2011). While there is some discussion in the NE literature about how governance needs to enable different responses according to local contexts and mechanisms to adjudicate between different perspectives (Richardson and Lefroy 2016), this discussion is fairly narrow and only hints at the need to address ‘fundamental influences’ on conservation and restoration such as social values (Collier 2015).

What is missing from this literature, and what can be done?

This section uses the framework to identify some of the neglected aspects of adaptive governance not covered in the current literature, and then links the findings of the review to the literature on governance reform to identify techniques that can be used to develop a reform agenda in specific contexts, as well as needs for further research.
4.1 Legal and policy reform

Among the five “sticking points” described here, several hinge on a mismatch between conservative frames and shifting reality; whether that be formal framing in policies and law or the cognitive frames of experts and the public. Re-framing what conservation means in the Anthropocene is essential to advancing the debate about NE. This will require reform to both law and policy, which will need to be complemented by re-allocation of effort and resources, although this will need to be done cautiously to avoid “opening the door to impunity” (Murcia et al. 2014). Some recommendations for accommodating NE in formal policies have been provided in the literature (e.g., Bridgewater and Yung 2013), but application in different landscape and cultural contexts remains an open question. Most countries, even those in Europe where concepts of nature are more human-centric compared with elsewhere, will need to amend legislation and policies to accommodate new ecological realities and reconcile them with social preferences for and institutional commitments to conservation.

Without re-framing, conservation will still largely focus on historical baselines (whether cultural or ecological), which neglects the reality of changing ecosystems and related values in legislation, management, and investment. In highly modified agricultural landscapes, for example, there may be few living examples of historical ecosystems, and failing to broaden notions of what is worth protecting neglects key drivers and ecosystems processes, leading to overall biodiversity losses at the landscape scale. There is a link here, too, to administrative competence, as investment is presently geared toward conventional approaches (e.g. protecting
species in concentrated pockets of landscapes). Yet changing environmental conditions in some landscapes require experimentation with more interventionist conservation policies and may benefit from more focus on restoration of function across broader spatial scales (Clement et al. 2017).

Reform could mean adopting objectives that focus on maintaining ecological functions or pursuing strategies that foster adaptation, either in association with or at odds with cultural preferences (e.g. reforesting moorland in the UK). Governing in the Anthropocene requires strategy beyond preserving specific assets and characteristics, and a focus on adaptive capacity and delivering ecosystem services (Bridgewater and Yung 2013). This approach could go some way to addressing confusion between means and ends (Wallace 2003), moving away from the focus on species composition and protecting rare assets, and can be a critical part of re-calibrating conservation objectives (e.g., climate-ready objectives Dunlop et al. 2013). Adopting the principles of reflexive law also offers a way to balance the necessity of certainty in decision making with the reality of complex ecosystem dynamics (Garmestani and Benson 2013). In reflexive law, thresholds and adaptive management principles can be built into the structures of formal institutions along with review mechanisms to ensure these are regularly reflected upon and revised to reflect new knowledge. Another way in which law could enable more flexible conservation interventions is to move toward more general principles (rather than specific rules) based legislation, which might focus on conserving ecological processes rather than particular species. This pathway would require careful
implementation, however, as greater flexibility has the potential to enable innovation but comes with the trade-off of less operational and legal certainty.

These formal approaches require explicit consideration of authority and power, which can help guard against unintended consequences potentially arising from acceptance of NE. Carefully considering framing (and re-framing) also enables pursuit of multiple solutions, including more conventional management practices and management frameworks that accommodate NE. Not only could this address concern that the latter will displace the former (Standish et al. 2013), but it also supports variety, important for resilience and building adaptive capacity of institutions (Gupta et al. 2010), especially buffering.

4.2 Connecting the formal to the informal

Reform cannot be limited to formal laws and policies if progress is to be made, however, as informal institutions are known to have equally strong influence on practice (Ostrom 2005). The extent to which informal pathways can support effective governance reform varies across contexts and is influenced by political factors shaping how formal policies are interpreted. In the USA, for example, conservation has been interpreted more broadly or narrowly by administrations over the years in practice, even with minimal changes to the legal framework (Cole and Yung 2010). Although the lack of consistency is challenging over the long term, it can also provide an opportunity to integrate innovative solutions, including proactive responses to transformation, into policy portfolios with minimal legal reform. In other places, e.g. Australia, this may be more problematic where framing relates
specifically to the management of listed Matters of National Environmental Significance, but there are signs that the reality of ecosystem transformation is creating a strong impetus to modernise conservation governance (e.g. Clement et al., 2017; Hughes et al., 2017; Wyborn et al., 2016).

Intentional effort to support buffering is another area of focus for governance reform. This effort includes strategies for including a wider variety of interventions into conservation practice, accommodating a broader range of conservation objectives, engaging multiple institutions (redundancy), and a focus on forecasting and responding to changes in the external environment (e.g. population growth, market forces, political pressure) (Boyd and Folke, 2011; Clement et al., 2016a; Elmqvist et al., 2003). Such strategies need not require dramatic changes to formal institutions, but can help conservation organisations more effectively achieve their objectives over the long term. The prospect of better buffering is, however, limited by knowledge, as current practice is necessarily based on disparate correlational data and there are significant challenges in predicting the specific ways in which ecosystems will change into the future (Purves et al., 2016). Such knowledge limitations compound uncertainty and complexity when considering how to respond to NE.

Policy and legal reform also cannot, in itself, address the vexed problem of how to reconcile diverse opinions about what biodiversity or landscapes are worth protecting. The NE literature often assumes culture is a barrier to change; however,
this is certainly not always the case, and there can be good cognitive fit between the way the problem is understood by key actors and the ecological reality in a particular landscape (Clement et al. 2017). There is also a constant interaction between governance and cultural norms, which helps facilitate informed discussion and may ultimately result in reconciliation. Biodiversity as a term and mainstream policy objective is but a few decades old, but its enshrinement in formal legal frameworks has contributed to its increasing cultural relevance. Governance provides a forum for bringing scientific knowledge to the community and in bringing stakeholder views into decision-making about how to adapt and respond to the emergence of NE. Ultimately, a more informed and nuanced understanding of how the public and individuals and organisations involved in conservation actually view NE and ecosystem transformation, rather than making assumptions about resistance (e.g. Hagerman and Satterfield 2014), is needed to support new policy objectives and management approaches. Additional research should be done to investigate this question across different cultural, legal, and ecological contexts.

4.3 Areas for further investigation

Our review also points to underexplored aspects in NE literature that could provide more guidance on what can be done. Focusing on interplay, for example, can reveal opportunities for governance reform by revealing conflicting and complementary demands and objectives. Interplay refers to the interactions between institutions and levels of governance (Young 2008). Interplay dynamics can have neutral, disruptive, or supportive effects on addressing environmental problems (Stokke 2011), and can be grouped into three types - functional, political, and regime
Functional interplay occurs when solving one problem affects another. With respect to NE, this could mean, for example, managing for an NE in one area causes pest problems in another area nearby. Political interplay can also occur because of competing or conflicting goals (e.g. economic development versus habitat protection) and such discordant approaches can vary at different levels of governance. Negative regime interplay could occur if efforts to formalise management of NE conflicts with other institutional regimes (e.g. property rights, economic structures, agriculture) (Vatn and Vedeld 2012; Young 2008). Conservation is often low on the political agenda and can conflict with more prominent goals (e.g. agricultural production), and conservation agencies often have complex, conflicting mandates that are difficult to reconcile (Cole and Yung 2010) or vary across jurisdictions (Clement et al. 2016a). At the same time, interplay can often reveal opportunities for cooperation and areas where conservation and development are complementary, and productive interplay dynamics are often central to achieving reforms in multi-level and networked governance regimes (Clement et al. 2015; Clement et al. 2017).

Governance reform has a particularly significant role to play in managing interplay dynamics. The range of issues relating to interplay with respect to NE is potentially wide and will vary across contexts, but in most situations governance actors will need to consider how managing NE conflicts or is complementary to achieving other objectives. For example, an NE might include alien species, but intentional governance reform can consider trade-offs and ensure formalised management of NE has positive net effects on biodiversity, climate resilience, and ecological
Conflicts arising from regime interplay might be resolved in part by intentional efforts by organisations to leverage political discourse to simultaneously achieve political goals and positive outcomes for ecosystems (i.e. institutional ambidexterity; Greenwood et al. 2011; Clement et al. 2016b). In reforming governance win-win scenarios might mean, for example, acknowledging that agricultural intensification is a primary goal in some landscapes, and adjusting the conservation focus to include management of NE. The net effect on biodiversity and key ecological attributes and processes (e.g., connectivity, resilience) would likely be positive as compared with trying to manage historical remnants, an assertion that could be tested in pilot projects prior to widespread implementation. Testing could be part of a broader strategy to leverage diversity that already exists into intelligently designed experiments in different jurisdictions or for different legislative mandates, where comprehensive reform is not feasible. In this way, testing could foster learning as well as enhancing capacity to buffer (Clement et al. 2016a; Cole and Yung 2010). There are many strategies for managing interplay dynamics that can build knowledge, new norms, and capacity for responding to environmental change (Oberthür and Stokke 2011). The specific ways in which interplay could be managed to improve fit will necessarily be context-specific, but it will in most cases be a central part of a governance reform agenda.

Adaptive capacity and greater flexibility implies a level of self-organising, another neglected area in the current NE literature. Self-organising refers to informal spaces where individuals and organisations share knowledge and experience, and make decisions as a network. Often contrasted with the top-down approach to decision-

...
making, such networks can build capacity for dealing with unknowns, store institutional memory and fill gaps in formal responsibilities (Boyd and Folke 2011). In dealing with novel ecosystems, as with biodiversity conservation in general, it will be necessary to establish central standards and policies to enable new decisions (e.g. choosing not to restore a system to its historical state). At the same time, there will need to be sufficient authority at the local level to pursue the most context-appropriate solution based on socio-economic and ecological conditions. These self-organising efforts are happening all over the world (Lorimer 2015), and make use of the principle of subsidiarity (i.e. devolved to the lowest governance level with the capacity to act). While an important source of knowledge about how to deal with novelty in conservation, such initiatives often diminish if they lack institutional support (Clement et al. 2017). Organisations with formal authority for conservation are well placed to support such efforts by providing knowledge and (where possible) resources. Ultimately, governance can ensure novel conservation projects still deliver valuable public goods by establishing key outcomes such efforts should achieve, even if they arrive there via a very different management pathway.

4.4 Guidance for approaching reform

While not a panacea for advancing the NE debate, there are a number of ways that governance reform can provide opportunities for bringing actors together to discuss values and scientific information, in order to establish new objectives for conservation fit for the Anthropocene. We have developed general guidance for how to approach governance and policy reform in a way that could advance the debate about how to manage change in transforming landscapes. Ultimately, reform must
be context specific and will need to occur at multiple scales (e.g. national, regional, and local). An outline of the key activities and techniques at the national and regional scale are provided in Table 1.

Table 1. Integrating novel ecosystems into biodiversity governance

<table>

This guidance does not provide a definitive answer to the sticking points discussed in the literature; but it draws on the content of the review to suggest tools and techniques related to governance, which can guide both research and practice. It also suggests the ways in which focusing on governance can help advance the debate about NE and enable new, fit-for-purpose conservation strategies. There is, of course, a strong need for productive interplay between governance levels. This includes insights on values, principles and priorities, as well as feedback on monitoring ecosystem change and subsequent interventions. Local learning about ecosystem dynamics will be critical for advancing knowledge about thresholds, which is a key concern in the NE literature, and could inform policy learning at higher levels, supported by the governance reforms discussed in Sections 4.1-4.3.

In developing this guidance, we have followed the structure of Fisher’s (2007) guidance for tiered, systematic decision-making, which helps highlight the interplay between governance levels and spatial scales. As governance reform is necessarily context specific, we have focused on identifying examples of approaches to support

(2014).
decision-making and capacity-building for addressing the challenges identified in this paper. We have included methodologies capable of building capacity relevant to governing NE, including the need to learn and test different options, cope with uncertainty, explicitly considering buffering and fostering self-organising; such as forecasting, backcasting, resilience assessment, informal network-building, and scenario planning (c.f. Peterson et al. 2003; Boyd and Folke 2011; Polasky et al. 2011). Collaborative planning methodologies (e.g. forums, citizens juries) have been selected for their value in building governance capacity, particularly adaptive capacity (c.f. Gupta et al. 2010; Berkes et al. 2003). Structured methods for environmental assessment and planning (e.g. Strategic Environmental Assessment, CAP, multi-criteria analysis) are included because they enable systematic consideration of different options and can be applied to both high-level decisions as well as specific projects and thus able to generate discussion about bigger picture policy and governance (Fischer 2007). Methods for bringing stakeholders together and accessing knowledge and values of experts and the public are included because this review suggests they need to be better understood (Section 4.2).

Our guidance draws on commonly used techniques that could be re-purposed to generate the discussions needed to inform intentional governance reform that is context specific. As well-accepted techniques, they are also able to provide outputs in a form ready to be fed back into decision-making and help to formalise new roles and responsibilities for dealing with transformation. While it is tempting to call for transformation of governance, such radical change is rare and extremely difficult to engineer (Scott 2014; Young 2008); however, building on existing institutional
structures and legacies can still lead to productive reform (Mitchell et al. 2016; Schoon 2013). Changes that are conservative at first may help guard against potential negative consequences discussed in the NE literature, and can also build the foundations for larger-scale changes that might be required in the future (Ansell 2011; Clement et al. 2015).

While reforms at the national level will influence action and drivers at the lower levels, we suggest it is at the regional level where the bulk of decision-making about what to do could occur in many countries. Although assessment and subsequent reform needs to be multi-scalar, the regional scale is where the specific attributes of social-ecological systems determine adaptive capacity and resilience (c.f. Walker et al. 2004). It is also a common scale for collaborative conservation efforts, and thus where the general vision can be translated to specific proposals for how to deal with ecosystem change (Johnson 2001). As compared with the national level, the regional level is also where stakeholder and community engagement becomes more concrete, as national priorities and local trade-offs (both conflicting and complementary goals for society, economy, and the environment) can be reconciled via detailed exploration (Faith and Walker 2002). Thus, focusing on regional governance could be productive, although this focus will of course need to be informed by principles developed at higher levels of governance. It also must be adapted for local conditions, depending on where the power, responsibility and authority for conservation are located, which could be more locally or at a national level in different contexts.
There are several well-developed tools that could help advance discussion about how to approach conservation in transforming landscapes at the regional level. Strategic Environmental Assessment, for example, is a process that can be applied to all decision-making tiers to analyse the impact of any changes to policies, plans and programs (Fischer 2007). While not used to its full potential as a strategic approach at present, it could be used to consider the big picture questions about what is driving transformation and considering options for how to respond and where resources should be focused. As a tool that is already embedded in many planning frameworks, it can support formal allocation of roles and responsibilities for dealing with the issues discussed in the NE literature. It can also specify feedback mechanisms not just to monitor, but to guard against potential negative consequences of accepting NE that were discussed in the literature.

Collaborative planning processes such as scenario planning can provide a way for imagining what novel ecological futures might look like, with the regional and local levels providing a manageable spatial focus. Such processes also provide a means to test how changing various aspects of governance can help steer toward a future with better biodiversity outcomes, as well as social and economic sustainability (Mitchell et al. 2016). Governance reforms might include enabling experimentation with novel and hybrid ecosystems in certain areas, giving responsibilities and authority to different organisations, creating new networks for learning and sharing information, or shifting accountability criteria to focus on achieving new or more flexible outcomes (Clement et al. 2015). Bringing scenario planning together with structured decision-making (SDM) processes is something that has not yet been done but could
provide a means to test different governance reform and management options (Lamers et al. 2014). SDM is a formal, staged approach for developing objectives and identifying optimal decisions for achieving them, based on known behaviour of ecosystems (Martin et al. 2009). The SDM methodology (Gregory et al. 2012) is best used to develop criteria to evaluate specific interventions in transforming landscapes, where consequences and trade-offs for socio-economic and ecological systems can be modelled and the required resources can be estimated. Citizens’ juries (Crosby 1995) are a largely unexplored method for dealing with the complex issues around ecosystem transformation. Such juries could bring experts to the public to discuss both the pros and cons of deliberatively pursuing NE as part of a new conservation toolkit. Citizens’ juries are particularly useful for focusing on specific governance reforms or management options that could be pursued, guiding a more collaborative approach to making decisions about the challenges discussed in this paper.

Central to governance is the question of who should be involved and when. Certainly national-level and supra-regional changes require cabinet-level support and should involve government agencies with formal responsibility. Governance explicitly calls attention to engagement beyond government, however, and activities at each level in Table 1 should involve analysis of existing roles and responsibilities beyond government to understand how they need to change for reform and implementation of new interventions to be successful. The engagement of experts (e.g. ecologists, legal scholars) is also critical to understand the technical issues with managing NE and reform of legislation to incorporate principles of reflexive law. Public
involvement at the national level would be necessarily broad and should include
provision of information on key issues and options prior to any surveys or
consultations. However, at the regional level there is the opportunity to engage the
public in more substantive and focused deliberations, as noted earlier.

More explicit response to what is being said in the governance literature can also
inform an agenda for reform. There is no single template for governance reform, but
allocation of authority and responsibility to new actors and directing resources to
novel interventions will likely be necessary in transforming landscapes. Although this
review provides guidance on some features of adaptive governance that will need to
be considered generally, a more thorough, context-specific assessment can identify
the specific features of adaptive governance that could be enhanced or reformed to
bolster adaptive capacity (Brunner 2010; Clement et al. 2017). Certain forms and
models of governance may not be able to help with the technical challenge of
creating a clear definition of NE and specifying the various degrees of ecosystem
change, but it can enable deliberation on this question in the process of policy
reform. These social challenges, combined with the technical challenges highlighted
in the NE literature (e.g. identifying thresholds, predicting future ecosystem
changes), suggest a more specific type of adaptive governance, adaptive co-
management, could provide principles for reform. Adaptive co-management puts
networks, diverse forms of knowledge and learning at the heart of governance
(Armitage et al. 2009), and could be a more fit-for-purpose governance form than
current top-down governance for addressing the sticking points discussed here. The
utility of these technical questions, which tend to be wedded still to static views of
ecosystems even in the NE literature, will also have to be revisited in light of a more
dynamic view of ecosystem management.

At the same time, there is a great deal of debate within the governance literature
about the practicalities of implementing adaptive governance and adaptive co-
management in practice, which aspects are most important for adaptation, and
which forms of governance and aspects of institutions are “best” for dealing with
transformation (e.g. Chaffin et al. 2014; Clement et al. 2015 & 2016a; Gupta et al.
2010; Koontz et al. 2015; Wyborn 2016). For example there is research supporting
the notion that adaptive governance supports management of multiple ecosystem
services and enables responses to ecosystem-wide changes, as well as supporting
collaboration across diverse interests, sectors, and institutional arrangements
(Schultz et al. 2015). Yet this same research highlights that trust and relationships
that are built through adaptive governance is not always robust enough when
challenged by internal and external political, environmental, and economic factors,
all of which are constant features of conservation in the Anthropocene. There is
some suggestion that it is better to think in terms of “knowledge governance” in
responding to ecosystem transformation, which draws attention to the fact that
there are many different options rather than a single right answer (Wyborn et al.
2016). Wyborn et al. instead suggest attention is paid to the processes that allow
conservation actors to draw on different values, rules, and knowledge and
strengthen those processes that support adaptation. This suggestion supports the
idea that reform is best focused on specific processes and features of governance,
rather than striving for a particular blueprint or governance mode.
Conclusion

Further significant ecological changes are likely given the intensity and pace of drivers of environmental change, but the relative pace of policy adaptation is slow and governance transformation difficult to engineer. To a large extent, conservation policy and practice is playing catch up with social and ecological change, and we can expect some resistance from practitioners, academics and the public, to the idea of NE for the foreseeable future while others will have accepted these changes as a new ecological reality that needs to be accommodated (Hobbs 2013). It is an open question as to whether concrete evidence on the irreversibility of ecological thresholds will help the grieving process or moreover, if we have time to await these data. Governance reform is not a cure-all, but it can be a source of adaptive capacity to help society and ecosystems cope with environmental change. Addressing the challenge of how to deal with NE requires an interdisciplinary approach in both research and practice, especially to foster closer connections between ecological research on the technical aspects of ecosystem transformation (e.g. questions about indicators, reference points, how to intervene to achieve particular goals, etc.) and governance research on the most promising leverage points for reform. Such connections are critical for advancing discussions about where, why, and how society should adapt to such transformative changes.

What is a diagnostic?
The framework is based on the diagnostic approach to analysis. This means it concentrates on whether governance is fit to achieve a purpose—in our case, biodiversity conservation. Fit can be considered in terms of space (are responses at the appropriate scale?), time (are responses happening at the right time and over the short-, medium-, and long-term?), or function (are actions directed at the right drivers?). Like a doctor diagnosing a patient, the diagnostic approach involves asking questions about current conditions in order to prescribe an appropriate course of treatment (Young 2008). The benefit of this approach is that it can be tailored to a specific context, and does not assume any single institutional design is ‘best’.

Conceptual Framework Components
The conceptual framework is organized as four broad categories: problem and players, politics, and two practice categories: competence and capacity (Table S1). Every component of this framework is built on the notion of fit; the analyst must consider how current institutions fit (or do not fit) with the ecological characteristics of the problem being managed. More information about each category is provided in Clement et al. 2016a.

</thead>
</table>
| **Power and authority:** Adaptive governance calls for greater power sharing, and devolving authority to appropriate levels. Institutions codify power relations and can block change, but also empower actors and enable collective action. | • Dynamics of power and influence  
• Authority  
• Roles and responsibilities |

**Category: Competence**

| Cooperation: Biodiversity attributes and threats occur across tenures and jurisdictions, requiring cooperation between actors and across scales and governance levels. | • Level of cooperation  
• Conditions supporting or hindering cooperation |
|---|---|
| Administrative competence: The translation of biodiversity conservation from paper to practice requires knowledge and capability. A shift to larger scale approaches requires commensurate resources and competencies. | • Human resources  
• Financial resources  
• Institutional and organizational practices |
| Learning: A deliberate process of adjusting goals and approaches in response to experience and information. It can enable change but also sustain practices. | • Feedback  
• Self-reflection  
• Systems understanding |

**Category: Capacity**

| Leadership and Entrepreneurship: Leadership can be structural, entrepreneurial and intellectual. It can come from any level of governance and provide important functions, including supporting innovation, providing vision, influencing culture, and supporting learning. | • Leadership types and influence institutional practices  
• Constraints on leadership capacity |
|---|---|
| Buffering: Institutions must be able to recognize thresholds and disturbances and respond adequately to buffer ecosystems. Organizations need to buffer against changes in the external environment to achieve objectives over the long term. | • Redundancy  
• Response diversity  
• Organizational buffering |
| Self-organizing: Self-organizing networks can build institutional memory, fill gaps in formal responsibilities, and provide backup capacity. | • Subsidiarity  
• Networks  
• Institutional support for self-organizing |
